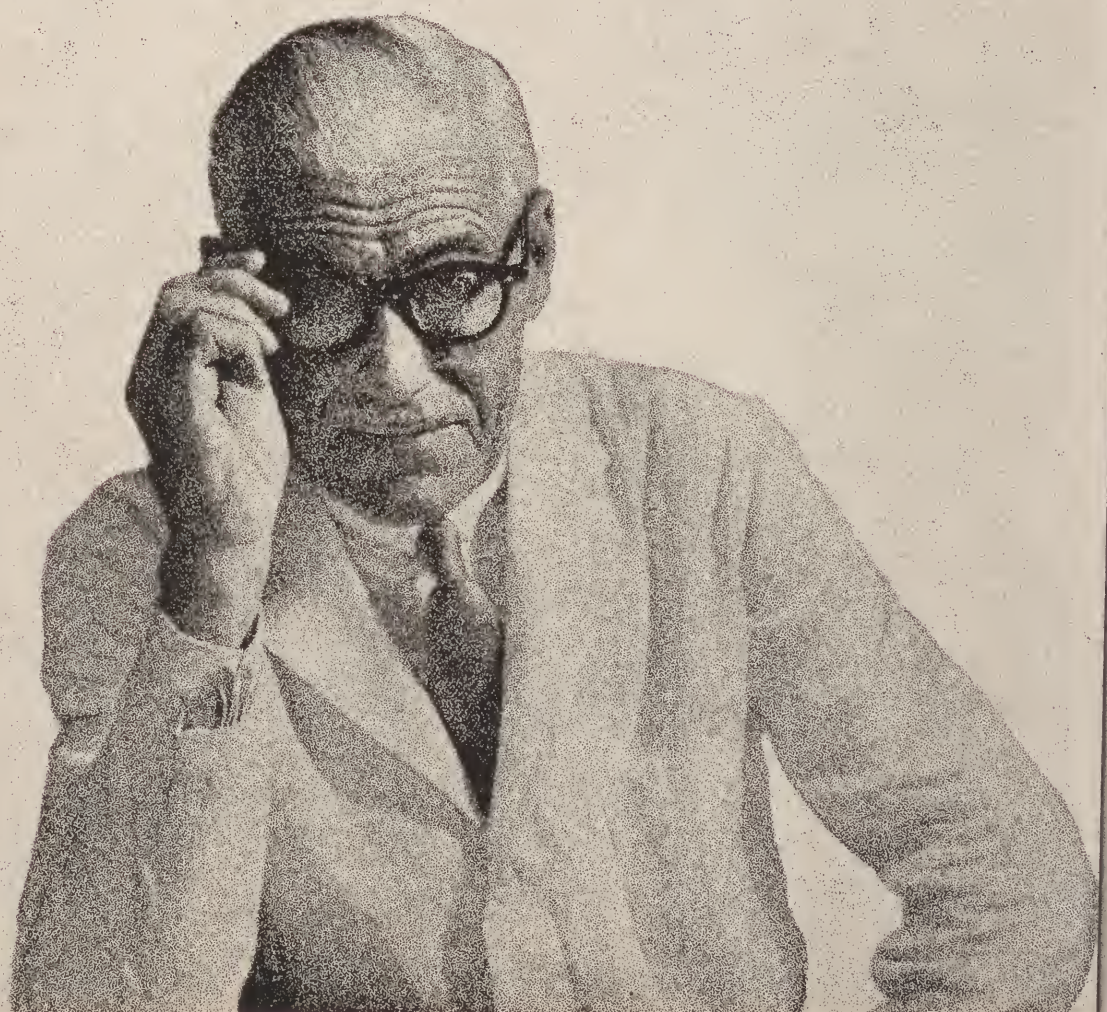
the "Action" gap

Of the more than 100 different types of cancer, colon and rectal cancers are unique for two compelling reasons:



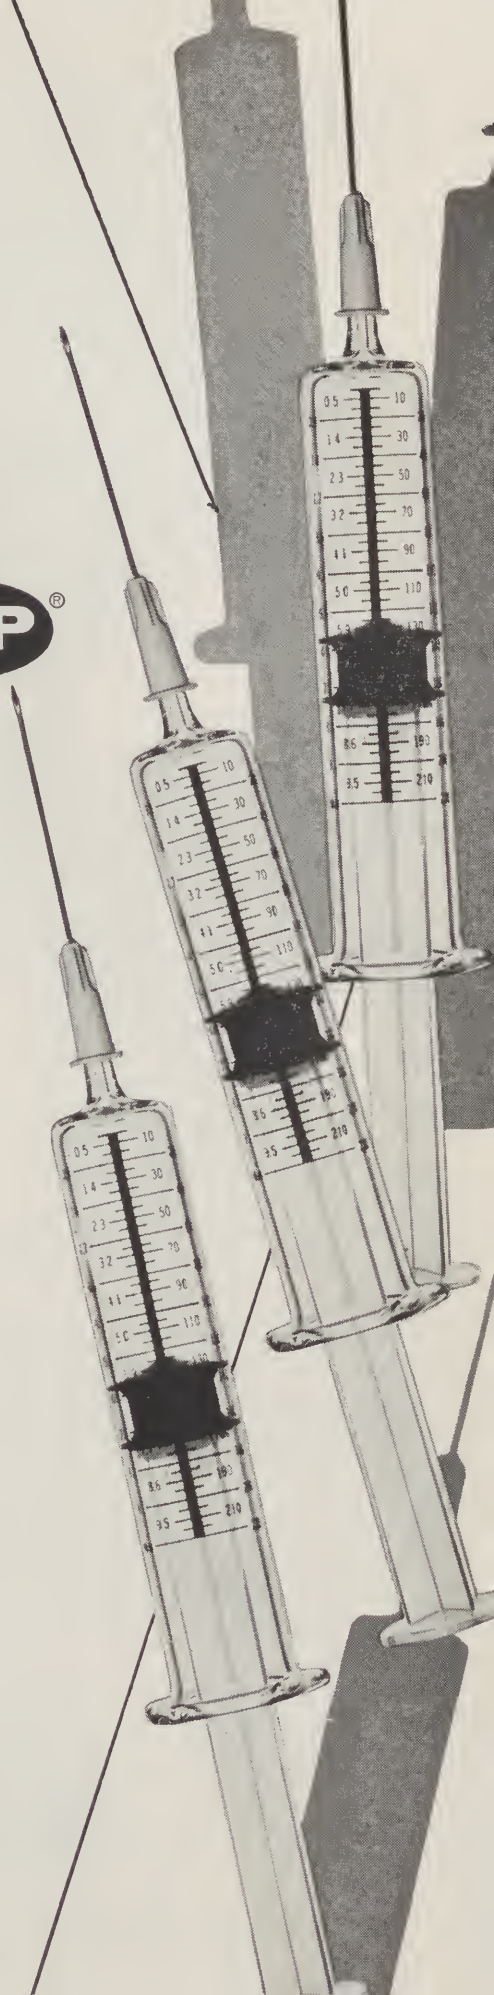
High incidence:	Annual new cases number about 73,000. Deaths now total 46,000 a year.
High curability potential:	Early diagnosis and prompt treatment could save almost 75%. Survival rate is now only 44%.

How to close the critical gap between possible and actual survivals?

The "procto" can today help save more lives from cancer than any other step in the checkup. Which is why, in our constant emphasis on the importance of annual checkups, we urge the inclusion of a "procto" ...and make available films and other pertinent materials for the layman and the physician. We *are* closing the "communications" gap.

Joint action by people and their doctors can help close the "action" gap to reach a cure rate of almost 75% for colon and rectal cancer.

American Cancer Society®



BSP® DISPOSABLE UNIT

HW&D BRAND OF SODIUM SULFOBROMOPHTHALEIN INJECTION, USP

(50 mg. per ml.)

BSP®

BROMSULPHALEIN®

IN A COMPLETE,

STERILE,

DISPOSABLE,

& ECONOMICAL

PATIENT-UNIT.

BSP, one of the more valuable single laboratory procedures for determining hepatic function, is now packaged in a complete individual patient-unit.

The BSP Disposable Unit contains a sterile syringe with the dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of terminally sterilized BSP solution. Each unit contains complete directions for use, precautions and contraindications.

This all-inclusive disposable put-up lessens the chance of cross-infection and saves time and labor — the most costly commodities.

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

b.i.d.

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

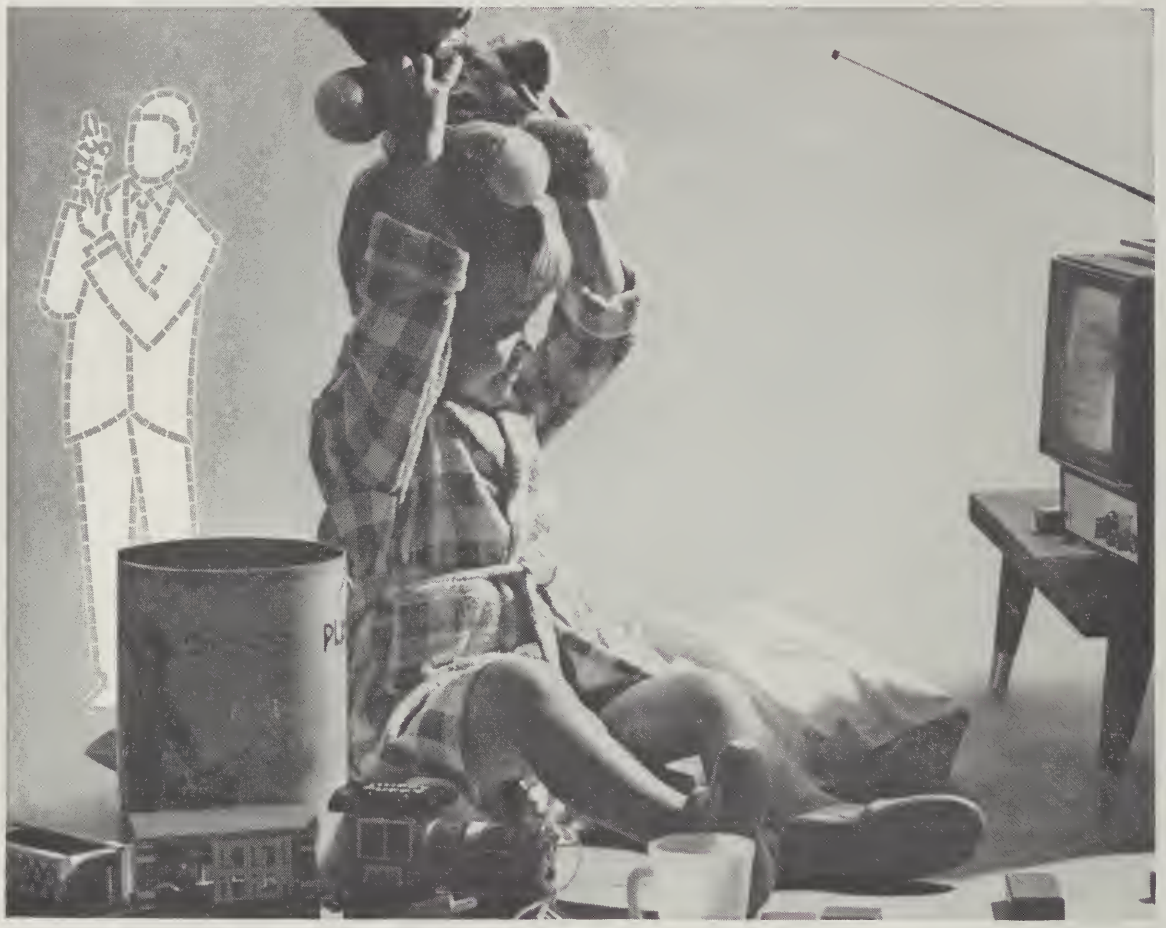
For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Effectiveness: Because its antibacterial component is DECLOMYCIN Demethylchlortetracycline, DECLOSTATIN should be equally or more effective therapeutically than other tetracyclines in infections caused by tetracycline-sensitive organisms. The antifungal component, Nystatin, protects against superinfection by antibiotic-resistant fungal overgrowth (particularly monilia) in the intestinal tract.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.



Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Demethylchlortetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

It's almost as if you were there to give an injection of penicillin

V-Cillin K®, Pediatric dependable oral penicillin therapy

Potassium Phenoxymethyl Penicillin

Description: V-Cillin K, the potassium salt of V-Cillin® (phenoxymethyl penicillin, Lilly), combines acid stability with immediate solubility and rapid absorption. Higher, more rapid serum levels are obtained than with equal oral doses of penicillin G.

Indications: Streptococcus, pneumococcus, and gonococcus infections; infections caused by sensitive strains of staphylococci; prophylaxis of streptococcus infections in patients with a history of rheumatic fever; and prevention of bacterial endocarditis after tonsillectomy and tooth extraction in patients with a history of rheumatic fever or congenital heart disease.

Contraindication: Penicillin hypersensitivity.

Warnings: In rare instances, penicillin may cause acute anaphylaxis which may prove fatal unless promptly controlled. This type of reaction appears more frequently in patients with a history of sensitivity reactions to penicillin or with bronchial asthma or other allergies. Resuscitative drugs should be readily available. These include epinephrine and pressor drugs (as well as oxygen for inhalation) for immediate allergic manifestations and antihistamines and corticosteroids for delayed effects.

Precautions: Use cautiously, if at all, in a patient with a strongly positive history of allergy.

In prolonged therapy with penicillin, and particularly with high parenteral dosage schedules, frequent evaluation of the renal and hematopoietic systems is recommended.

In suspected staphylococcus infections, proper laboratory studies (including sensitivity tests) should be performed.

The use of penicillin may be associated with the overgrowth of penicillin-insensitive organisms. In such cases, discontinue administration and take appropriate measures.

Adverse Reactions: Although serious allergic reactions are much less common with oral penicillin than with intramuscular forms, manifestations of penicillin allergy may occur.

Penicillin is a substance of low toxicity, but it possesses a significant index of sensitization. The following hypersensitivity reactions have been reported: skin rashes ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; and reactions resembling serum sickness, including chills, fever, edema, arthralgia, and prostration. Severe and often fatal anaphylaxis has occurred (see Warnings). Hemolytic anemia, leukopenia, thrombocytopenia, and nephropathy are rarely observed side-effects and are usually associated with high parenteral dosage.

Administration and Dosage: Usual dosage range, 125 mg. (200,000 units) three times a day to 500 mg. (800,000 units) every four hours. For infants, 50 mg. per Kg. per day divided into three doses.

See package literature for detailed dosage instructions for prophylaxis of streptococcus infections, surgery, gonorrhea, and severe infections.

How Supplied: Tablets V-Cillin K® (Potassium Phenoxymethyl Penicillin Tablets, U.S.P.), 125 mg. (200,000 units), 250 mg. (400,000 units), and 500 mg. (800,000 units).

V-Cillin K® (potassium phenoxymethyl penicillin, Lilly), Pediatric, for Oral Solution, 125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc. of solution (approximately one teaspoonful). [042567A]

1969 DUES BILLS IN MAIL

1969 Dues bills have been mailed to all members and are payable before JANUARY 31, 1969, in order to be eligible for legal defense in the event of suit being filed.

Legal defense includes the provision of a panel of expert medical witnesses to evaluate the merits of the case; as well as having these witnesses available to testify in court, if needed. Legal counsel is also provided and paid from Faculty funds.

The Council of the Faculty has ruled that strict interpretation of the bylaws must be followed. Late payment of dues precludes provision of this membership benefit.

DOCTORS OF OSTEOPATHY LICENSED

A total of 15 Doctors of Osteopathy have been licensed to practice medicine and surgery in Maryland. Professional association with these individuals is permissible, provided the cultist aspects of Osteopathy have been abandoned by those involved.

Those so licensed are: Drs. Christopher L. Ginn, John M. Gustin, Joseph W. Lindstrom, Richard C. MacDonald, Bertram H. Waskey, Millard Bass, all of Baltimore; Laurence R. Bower, Silver Spring; Murray Goldstein, Bethesda; Chester L. Bailey, Kensington; Robert B. Liskey and Robert C. Snavely, Hagerstown; Joseph C. Snyder, Bozman; Basil Tully, Chestertown; Ernest R. MacDonald, Annapolis; and Victor F. Brennan, Glen Burnie.

PUBLIC SPEAKING COURSE

A one-day public speaking course will be held under the auspices of the Public Relations Committee of the Faculty on Thursday, March 13, 1969, from 9:00 a.m. to 5:00 p.m. Registration is limited and those interested should contact the Faculty office promptly to indicate their wish to attend.

GRANTS AVAILABLE

Grants now available include a Fellowship in Business-Government Relations at the American University's School of Business Administration, Washington, D.C. The American Medical Political Action Committee will

GRANTS AVAILABLE (cont'd)

provide a graduate scholarship in the amount of $4,500 to anyone working toward a masters or PhD degree.

The Maryland Chapter, American Cancer Society, has available travel grants for physicians to acquire particular skills with respect to research, specific diagnostic techniques or specific therapy as related to neoplastic disease. The travel fellowship can provide transportation and room and board to those physicians who due to budgetary restrictions, find travel money unavailable for this type of study. The grant applicant must be a medical educator at a recognized teaching institution or community hospital in Maryland.

REFERENCE COMMITTEE MEETING

The Reference Committee meeting date has been set for

THURSDAY, MARCH 20, 1969

at 8:00 p.m., in the Faculty building, at which time any resolutions for consideration by the Annual Session of the House of Delegates will be discussed. All members in good standing are invited to attend this session.

CONGRESS ON SOCIOECONOMICS OF HEALTH CARE

The third national Congress on the Socioeconomics of Health Care has been scheduled for March 28 and 29, at the Palmer House, Chicago, Illinois. Full details may be obtained from the AMA or the Faculty office.

MED-CHI RETIREMENT FUND

The net asset value of the Med-Chi Members Retirement Fund has increased 15.28 % for the period January 1, 1968, through October 31, 1968.

MEDICAL SCHOOL INCREASE

The Carnegie Commission on Higher Education has called for new and expanded facilities to increase the supply of medical students by 75% by 1976.

The proposal calls for Federal grants to cover the entire cost of creation of the new places, as well as start-up grants to build about 20 new medical schools, at a rate of four to five per year for five years. Grants to students, depending on need, will be as much as $3,500 per year; in addition to grants per student to the institutions.

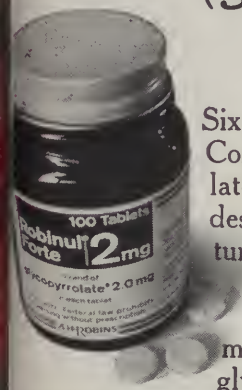
Phone: 669-9300 **Baltimore, Md. 21216**

Summation:
In addition to its primary indications for duodenal and gastric ulcer, Robinul Forte (glycopyrrolate) is indicated for other G-I conditions that may benefit from anticholinergic therapy. Robinul-PH Forte (glycopyrrolate 2 mg. with phenobarbital) is indicated when these situations are complicated by mild anxiety and tension.

Contraindications: Glaucoma, urinary bladder neck obstruction, pyloric obstruction, stenosis with significant gastric retention, prostatic hypertrophy, duodenal obstruction, cardiospasm (megaesophagus), and achalasia of the esophagus, and in the case of Robinul-PH Forte, sensitivity to phenobarbital.

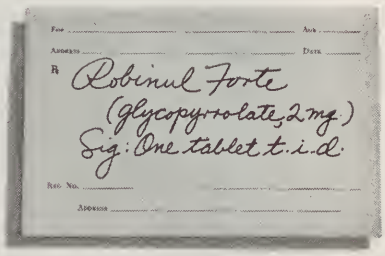


Precautions: Administer with caution in the presence of incipient glaucoma.

Adverse Reactions: Dryness of the mouth, blurred vision, urinary difficulties, and constipation are rarely troublesome and may generally be controlled by reduction of dosage. Other side effects associated with the use of anticholinergic drugs include tachycardia, palpitation, dilatation of the pupil, increased ocular tension, weakness, nausea, vomiting, headache, dizziness, drowsiness, and rash.

Dosage: Should be adjusted according to individual patient response. Average and maximum recommended dose is 1 tablet three times a day; in the a.m., early p.m., and at bedtime. See product literature for full prescribing information. Supply: Robinul (glycopyrrolate 1 mg.): Robinul Forte (glycopyrrolate 2 mg.); Robinul-PH (glycopyrrolate 1 mg.) with phenobarbital 16.2 mg. (Warning: may be habit forming); Robinul-PH Forte (glycopyrrolate 2 mg.) with phenobarbital 16.2 mg. (Warning: may be habit forming), in bottles of 100 and 500 tablets. A. H. Robins Company, Richmond, Va. 23220.

A·H·ROBINS



In peptic ulcer therapy, won't you give Robinul® Forte a Fair Trial?
(glycopyrrolate)

Six years ago the A. H. Robins Company introduced glycopyrrolate, a unique anticholinergic agent described in the prescribing literature as more closely approaching the ideal compound for controlling gastric hyperacidity and hypermotility of the G-I tract. Although glycopyrrolate (Robinul Forte) found good acceptance among numerous physicians, many others just didn't seem to want to give it a try, probably because the anticholinergic they were already using was giving acceptable results.

However, we believe you'll agree there's always room for a better anticholinergic. This is why we're asking you to give Robinul Forte a fair trial. Robinul Forte exerts a highly specific antisecretory action and marked inhibitory effect on intestinal tone. We're convinced you'll agree that this is indeed an outstanding drug when you observe its outstanding suppression of ulcer symptoms. Furthermore, it is unique in that it reduces intestinal tone, yet has little or no effect on peristalsis. In addition, the incidence of the more bothersome peripheral side effects is low.

No longer does the physician have to look for extreme dry mouth as the measure of his anticholinergic's effectiveness. The only way we can demonstrate to you firsthand the efficacy of glycopyrrolate (Robinul Forte) is for you to try it in your practice. That's why we're asking you to give it a Fair Trial. How can you give it a Fair Trial? You do it this way:

First: When you see your very next ulcer patient, write him a script as shown.

Next: Wait 10 days or until your patient comes in for his next appointment and get his "verdict" as to how he feels. Examine all the evidence and make your evaluation of his condition.

Finally: Render **your** verdict. If it's "significant improvement and marked relief of symptoms," then we believe you'll agree that Robinul Forte has proved its worth, and we rest our case. If not, consider our case for Robinul Forte closed. That's a Fair Trial, Doctor, and it's all we ask.

Robinul® Forte
(glycopyrrolate, 2 mg.)

The summation is an important part of every case. You'll find ours on the preceding page, Doctor.

Insight into Escalating Hospital Costs

Employee dishonesty, waste and indifference constitute an ever increasing portion of the rise in hospital costs, the president of a New York based consulting firm reported during last year.

Some of the aforementioned problems, frequently overlooked by the hospital administrator, revealed in a nationwide study are startling.

For example, losses due to employee theft have more than doubled in the last three years; supervisors, technicians and professional personnel are increasingly, and more significantly, involved in dishonesty and manipulations; the most costly, and yet most difficult defalcations for management to detect, are those occurring in purchasing, cashiering, pharmacy and central supply. Equally harmful are losses of supplies and material experienced in maintenance, dietary and laundry departments. Also noteworthy is the conflict of interest that emanates from laboratory and radiology services, and from research projects.

Another fact revealed in the study is that recent wage increases of historic dimensions have resulted in only marginal productivity gains.

The opportunities for theft, waste, collusion and all imaginable forms of malpractice in this more than 8 billion dollar a year industry stagger the imagination. Theft in supplies, equipment, food, drugs, narcotics and expendable goods intended for patients has become commonplace.

Recognizing there are probably no more dedicated and harder working executives with a more vital degree of responsibility than hospital administrators, the survey continued, hospital costs, nevertheless, have increased 51.8% in the past three years, and will continue to increase in view of the hospital's ever expanding role in community affairs.

"The best untapped avenue of expense reduction and improved productivity is preventive management," the report stated. "By focusing on inventory losses and personnel performance, executives get to the heart of their problems. In addition to employee dishonesty, administrators uncover systems breakdowns, supervisory failures, rank and file inefficiencies, nursing shortcomings and poor employee morale—all causes of rising costs and patient neglect."

The need to know what is really going on beneath the surface is highlighted when management engineers undertake performance audits, systems surveys and inventory control projects. In more than 50% of these cases, with no prior indication that dishonesty existed, fraud, inventory manipulations, falsifications of records, kickbacks and other forms of dishonesty have been uncovered. Obviously, management cannot make a sensible decision merely by studying comparative statistics concerning past performance.

Adequate controls neither end nor begin with the locking of doors, issuing passes, uniformed guards, or even firing a dishonest employee accidentally caught. The problem instead is really one of human relations and human behavior. "It may be more difficult to read the subtle barometer of employee behavior than to interpret a profit and loss statement, but the one requires as much scrutiny and concern as the other.

"Only when management learns what is really going on can it take corrective action and establish an atmosphere showing that management is alert and cares. When indifference and dishonesty run rampant, top executives are at fault if they tolerate it, and in danger if they do not control it."

"All Interns are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards; they all are underpaid, too. Therefore, all interns are alike.

That's utter nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all interns aren't alike, either.

AMA, Better Business Bureau: Decade Of Cooperatively Combating Quackery

From the snake oils, elixirs, and nostrums of the past, health quacks have moved to more sophisticated pseudomedications, often more powerful and more dangerous, the president of the National Better Business Bureau said recently.

"What was once 'magnetic' or 'galvanic' is now 'electronic' or 'radioactive,' and what was once touted as a new 'natural' discovery is now promoted as a new 'laboratory' discovery," Richard Maxwell told the Fourth National Congress on Health Quackery, meeting at the Drake Hotel.

Mr. Maxwell, a business executive before assuming the NBBB position in New York in June, told the American Medical Association-National Health Council conference:

"According to some reports, quackery today brings in close to a billion dollars annually to its practitioners. Our modern medical quacks are quite aware of legal loopholes and are often fortified by dubious 'clinical support' for their claims."

A decade ago, Mr. Maxwell pointed out, a special program for correcting deceptive or misleading advertising in the health field was instituted with the aid and support of the American Medical Association, other professional groups, and private industry.

"We, therefore, celebrate today ten years of fruitful cooperation with the American Medical Association, a great organization for its profession and one which has supported us with funds and professional counsel," he said.

In recent years the annual volume of complaints and inquiries has ranged between 5,000 and 6,000 at the National Better Business Bureau alone.

"The bulk of complaints involves a relatively small number of products, principally vitamin-mineral compounds, weight controllers, devices for massage, hair removal, mechanical aids for hernias, and hearing devices.

"Within the last year, the problems associated with wigs and wiglets, garments claimed to be weight-reducing aids, smoking deterrents, and a new crop of wrinkle-removing cosmetics, have occupied our time.

"The proportion of complaints received by the Bureau doubtless understates their magnitude generally because many are handled directly or through local bureaus. Moreover, experience suggests that dissatisfaction with products and methods of a personal variety, such as rejuvenators, hair and scalp treatments, remedies for 'female troubles,' and for certain emotional or mental problems, and professional services, often do not result in letters of complaint."

See next page for prescribing informati

You've made it one of your specifics in acute otitis media

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

You've made it one of your specifi in acute otitis medi

DECLOMYCIN acts against many strains of H. influenzae, pneumococci and streptococci, m most common invaders. In otitis media, where is difficult to isolate the causative organism, th coverage may be important. However, some str may be resistant and other pathogens can be involved.

You've found the high serum levels of DECLOMYCIN important, too. Its prolonged ac permits convenient 300 mg b.i.d. or 150 mg q.i.d. administration.

When specimens are obtainable, your culture studies will indicate the usefulness of DECLOMYCIN.

Effectiveness: DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines in infections caused by organisms sensitive to the tetracyclines.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enteroc ti pruritus ani. Skin—maculopapular and erythematous rashes; aa case of exfoliative dermatitis has been reported. Photosensiti onycholysis and discoloration of the nails (rare). Kidney—rise in U apparently dose-related. Transient increase in urinary output, sm times accompanied by thirst (rare). Hypersensitivity reactions—ri caria, angioneurotic edema, anaphylaxis. Teeth—dental staining ye low-brown) in children of mothers given this drug during the latte na of pregnancy, and in children given the drug during the neonatal pe od, infancy and early childhood. Enamel hypoplasia has been se a few children. If adverse reaction or idiosyncrasy occurs, discon u medication and institute appropriate therapy. Demethylchlort ra cycline may form a stable calcium complex in any bone-forming t su with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Sh u be given 1 hour before or 2 hours after meals, since absorpti impaired by the concomitant administration of high calcium co drugs, foods and some dairy products. Treatment of streptoc infections should continue for 10 days, even though symptoms subsided.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Capsules: 150 mg; **Tablets:** film coated, mg, 150 mg and 75 mg of demethylchlort cycline HCl.

LEDERLE LABORATORIES, A Division of
American Cyanamid Company, Pearl River, New York

Lederle

heavenly relief
for unearthly cough

Benylin®
EXPECTORANT

Each fluidounce contains: 80 mg. Benadryl® (diphenhydramine hydrochloride, Parke-Davis); 12 grains ammonium chloride; 5 grains sodium citrate; 2 grains chloroform; 1/10 grain menthol; and 5% alcohol.

An antitussive and expectorant for control of coughs due to colds or of allergic origin, BENYLIN EXPECTORANT is the leading cough preparation of its kind. BENYLIN EXPECTORANT tends to inhibit cough reflex... soothes irritated throat membranes. And its not-too-sweet, pleasant raspberry flavor makes BENYLIN EXPECTORANT easy to take.

PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this preparation. Hypnotics, sedatives, or tranquilizers if used with BENYLIN EXPECTORANT should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENYLIN EXPECTORANT.

ADVERSE REACTIONS: Side reactions may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, and blurring of vision have been reported. Allergic reactions may occur.

PACKAGING: Bottles of 4 oz., 16 oz., and 1 gal.

Parke, Davis & Company

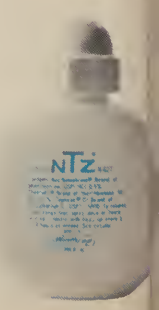
"The inconvenience of a cold"

For a cold, NTz® Nasal Spray provides rapid relief of nasal symptoms. Relief starts with the first spray which opens the inferior part of the common meatus. A second spray, a few minutes later, will shrink the turbinates to help provide sinus drainage and ventilation. Dosage may be repeated every three or four hours as needed, for temporary relief of symptoms. NTz is well tolerated but overdosage should be avoided.

As a sinusitis deterrent, NTz Nasal Spray can be used to keep the nasal passages open during a cold to help prevent development of acute sinusitis—or to help prevent the acute condition from becoming chronic.



Supplied: NTz Nasal Spray, plastic squeeze bottles of 20 ml.; NTz Nasal Solution, bottles of 30 ml. (1 fl. oz.) with dropper.

NTz is more than a simple vasoconstrictor. It contains

Neo-Synephrine® (brand of phenylephrine) HCl 0.5 per cent, the major component, virtually synonymous with fast, efficient but gentle nasal vasoconstriction.

Thenfadil® (brand of thenyldiamine) HCl 0.1 per cent, topical antihistamine for reduction of rhinorrhea, sneezing or itching. It combats the allergic reactions that may occur in colds or sinusitis.

Zephiran® (brand of benzalkonium, as chloride, refined) 1:5000, antiseptic preservative and wetting agent to promote penetration and spread of the formula.

Winthrop Laboratories, New York, N.Y. 10016 Winthrop

"With this diet you can eat anything you like, here's a list of the things you like!"

OBETROL® for weight control

Each OBETROL-10 tablet contains: Methamphetamine Saccharate 2.5 mg.; Methamphetamine Hydrochloride 2.5 mg.; Amphetamine Sulfate 2.5 mg.; Dextro-amphetamine Sulfate 2.5 mg.; (OBETROL-20 tablets contain twice this potency) Pat. #2748052.

This combination of amphetamines may be useful as an adjunct in the management of certain forms of obesity where an appetite depressant is indicated.

Contraindications: Hypertension, advanced arteriosclerosis, coronary artery disease, cardiac arrhythmias, peripheral vascular disease, states of undue restlessness, anxiety, excitement, agitated depression, hyperthyroidism, idiosyncrasy to amphetamine, concomitant administration of a monoamine oxidase inhibitor. **Precautions:** Use with caution in individuals with anorexia, insomnia, vasomotor instability, asthenia, psychopathic personality, a history of homicidal or suicidal tendencies, and individuals who are known to be hyperractive to sympathomimetic agents, or emotionally unstable individuals who are known to be susceptible to drug abuse. Certain monoamine oxidase inhibitors may potentiate the action of Obetrol. **Side Effects:** The most common side effects attended with the use of amphetamines include nervousness, excitability, euphoria, insomnia, dryness of mouth, nausea, vertigo, constipation, and headache.

Dosage and Administration: Initial adult dose is one-half to one 'Obetrol-10' tablet daily, preferably one-half to one hour before meals. This may be gradually increased to one 'Obetrol-10' or 'Obetrol-20' tablet one to three times daily as indicated. **Supplied:** Tablets scored, in bottles of 100. 500, and 1000.

171st Annual Meeting

More prominent speakers* who will present papers during the Annual Meeting in April include Milton Helpern, MD, and Joseph Lee Hollander, MD.

Official investigation of *Sudden, Suspicious and Violent Deaths: A Community Responsibility,* is the title of the presentation by **Milton Helpern, MD,** to be given during the scientific sessions at Annual Meeting.

Dr. Helpern

At present, Dr. Helpern is Chief Medical Examiner of the City of New York; Professor and Chairman of the Department of Forensic Medicine at the New York University School of Medicine, and Lecturer in Legal Medicine and Visiting Professor of Pathology at Cornell University Medical College.

Dr. Helpern, who was born and educated in New York City, received his medical degree from Cornell University Medical College. In 1929 he was elected a diplomate of the National Board of Medical Examiners, and his specialty board certifications include the American Boards of Pathology, Pathologic Anatomy, and Forensic Pathology. He is a consultant in pathology and forensic pathology at the Armed Forces Institute of Pathology, the Bureau of Medicine of the Food and Drug Administration, the Criminal Justice Coordinating Council of New York City, as well as several other agencies and various hospitals.

He is past president of numerous medical societies and is president of the Alumni Association of Cornell University Medical College, the International Association of Accident and Traffic Medicine and the National Association of Medical Examiners. His honorary memberships include both national and international organizations. Dr. Helpern is co-author of *Legal Medicine, Pathology and Toxicology,* and author of approximately 60 articles on medical-legal subjects. Currently, he is involved in several research projects.

Joseph Lee Hollander, MD, will speak on *Intrasynovial Corticosteroid Therapy in Arthritis* in April.

Dr. Hollander

Born in Ferguson, Missouri, Dr. Hollander obtained his secondary education there. He received his AB from Cornell University, and in 1935 he was awarded his MD from the University of Pennsylvania School of Medicine. Dr. Hollander served both his internship and residency at the Pennsylvania Hospital in Philadelphia, where he directed an arthritis clinic until he entered the armed forces in 1942. After his discharge in 1946, he became a member of the faculty of the University of Pennsylvania School of Medicine and was appointed Professor of Medicine in 1962. He has been Chief of the Arthritis Section at the University Hospital since 1946.

Dr. Hollander has been Editor-in-Chief of *Arthritis and Allied Conditions* since 1948, and his research group has pioneered in joint physiology, intra-articular corticosteroid injections, synovial fluid analysis, and the immunopathogenesis of rheumatoid arthritis.

He is a past president of the American Rheumatism Association and is an honorary member of many international rheumatism societies.

* See the December Journal for capsule biographies of **Robert L. Evans, MD,** and **Howard W. Jones, Jr., MD,** who also will be featured during the scientific sessions of Annual Meeting in April.

JANUARY 31, 1969—12:30 P.M.

IRON DEFICIENCY

C. Lockard Conley, MD
Professor of Medicine
The Johns Hopkins University School of Medicine

The causes, manifestations and clinical implications of iron deficiency will be discussed and illustrated by representative cases. Emphasis will be placed on differential diagnosis and treatment. Discussion will include the economical and appropriate use of laboratory tests and their interpretation.

Sponsor: Greater Baltimore Medical Center
Replays: Monday, February 3, 1969 12:30 P.M.
Wednesday, February 5, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

FEBRUARY 7, 1969—12:30 P.M.

CONSTRICTIVE AND RESTRICTIVE HEART DISEASE

Kenneth B. Lewis, MD
Assistant Professor of Medicine
The Johns Hopkins University School of Medicine, and
Assistant Chief of Medicine,
Baltimore City Hospitals

This discussion will review briefly the typical presentation of patients with constrictive pericardial disease and will then emphasize several unusual ways in which this entity may be present. The difficulty in separating, on clinical examination and even at times on laboratory evidence, constrictive pericardial disease for which surgical therapy offers chance for improvement from restrictive myocardial disease for which there is no specific treatment will be discussed. The current diagnostic methods for evaluating patients suspected of having this form of heart disease will be reviewed.

Sponsor: Easton Memorial Hospital
Replays: Monday, February 10, 1969 12:30 P.M.
Wednesday, February 12, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

FEBRUARY 14, 1969—12:30 P.M.

VENOUS VASCULAR DISEASE

J. Alex Haller, Jr., MD
Associate Professor of Pediatric Surgery
The Johns Hopkins University School of Medicine

This talk will be on the pathophysiology and management of deep thrombophlebitis and will include the treatment of thromboembolism, massive venous occlusion, and the post-phlebitic limb. The operative and non-operative treatment of deep thrombophlebitis will be discussed and pertinent case material will be included.

Sponsor: Provident Hospital
Replays: Monday, February 17, 1969 12:30 P.M.
Wednesday, February 19, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

FEBRUARY 21, 1969—12:30 P.M.

HYPERTENSION

R. Patterson Russell, MD
Assistant Professor of Medicine
The Johns Hopkins University School of Medicine

In considering treatment of the hypertensive patient the following will be reviewed: role of the initial evaluation; aims of and indications for treatment; currently effective pharmacotherapeutic agents and results of therapy.

Sponsor: Baltimore County General Hospital
Replays: Monday, February 24, 1969 12:30 P.M.
Wednesday, February 26, 1969

Legs don't come in exact sizes

No two legs are alike . . . not even on the same patient, and the usual "small, medium and large" sizes of elastic stockings will not be effective for the majority of your patients.

That's why *Jobst Venous Pressure Gradient®* supports are custom-made, and precisely fitted to the individual patient with a long series of careful measurements.

Even more *important* than the perfect fit, are the *exact* counterpressures built-in to your own prescription!

Jobst Venous Pressure Gradient® elastic stockings are a treatment of *choice* for leg ulcers, varicose veins, stasis dermatitis, postmastectomy lymphedema, post-phlebitis syndrome, post-fracture, post-operative and injury edema.

For full information, have your secretary mail the coupon below. Or if you have an immediate problem, just call the number on the coupon. You will find out why we named them "Service" Centers.

Jobst Service Center, Suite 415, Medical Arts Bldg., 101 W. Read St. Baltimore 21201, Phone (301) 539-0560

HOME OFFICE—BOSTON, MASS.

CANCER, A MANUAL FOR PRACTITIONERS, fourth edition, published by the American Cancer Society, Boston, Mass. 1968.

Each chapter of this publication has been completely revised and rewritten by recognized authorities in the diagnosis and treatment of cancer.

The purpose of this manual is to aid practitioners in the early diagnosis of cancer and to give them an understanding of its treatment and prognosis. Diagnosis is stressed but no attempt is made to go into the technical details of cancer therapy.

SYNOPSIS OF SURGERY, Richard D. Liechty, MD, and Robert T. Soper, MD; The C. V. Mosby Company, St. Louis, Mo. 1968.

This book was conceived in the light of the inevitable change in both medical school teaching and the textbooks of medicine. The authors state that basic clinical subjects must be taught as "core courses" to provide time for individual study and textbooks must adapt to this evolution in medical education.

The concept of teaching the essentials of surgery to the beginning student in the field, whether he is in medical school or many years out of school, is effectively put across in this volume.

SYMPOSIUM ON OCULAR THERAPY, Irving H. Leopold, MD; The C. V. Mosby Company, St. Louis, Mo. 1968.

This publication records the information presented at the Drug Symposium of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology meeting held in Chicago in the fall of 1967.

All the presentations are current and differ from those of earlier volumes. The material has been kept practical, fundamental, and timely; also, the Symposium is published every year; so the data is current and available to all those interested in it.

BRAY'S CLINICAL LABORATORY METHODS, John D. Bauer, MD, Philip G. Ackerman, PhD, and Gelson Toro, PhD; The C. V. Mosby Co., St. Louis, Mo. 1968.

This new edition has been extensively revised and updated, the source material being lectures given to residents in clinical pathology. Obsolete and out-of-date material has been eliminated.

Those with reference libraries would do well to purchase this book to be sure they have the most current literature available in this area.

HANDBOOK OF PEDIATRIC MEDICAL EMERGENCIES by Charles Varga, MD; The C. V. Mosby Co., St. Louis, Mo. 1968.

This is the fourth edition of this book which is now as current as medical literature can be on the subject. Ten of the chapters have been completely rewritten and most of the contributions in this edition are new.

The author points with some pride to the fact that the reorganization of the book is due in part to his experiences with his son's emergencies which "first taught me what it really means to be an anxious parent."

This is a worthwhile addition to any medical library.

SURGICAL PATHOLOGY by Laurence V. Ackerman, MD, and Harvey R. Butcher, Jr., MD; The C. V. Mosby Company, St. Louis, Mo. 1968.

This fourth edition of Surgical Pathology has been extensively revised. The section on tumors of the skin has been completely rewritten; and the place of electron microscopy in surgical pathology has again been included and expounded upon.

The book can only be an introduction to the vast field of surgical pathology: the pathology of the living. It does not pretend to replace in any way the textbooks of general pathology, its purpose being merely to supplement them.

The contents are not as complete as they might be because emphasis has been placed on the common rather than the rare lesions and are, to a great extent, based on the author's personal experiences.

New practice?
Heel thyself.
And the best way to do the heeling is with a Professional Loan from Mercantile-Safe Deposit and Trust Company. The Mercantile Professional Loan is especially designed to help you through the financial rough spots of properly outfitting a modern office.
You can get all the details by calling (823-7400) or by writing: Ed Mullendore or Phil Cassidy; Mercantile-Safe Deposit and Trust Company; Professional Department; 409 Washington Avenue; Baltimore, Maryland 21204.
Let "The Merc" heel you quickly. And keep you heeled with a sensible repayment plan.
MERCANTILE-SAFE DEPOSIT and TRUST COMPANY

THE MONTH IN WASHINGTON

The incoming Administration work on a health program was started with President-elect Richard Nixon's appointment of John Dunlop, a Harvard University professor, to head a special task force.

Dunlop, 54, is a prominent economist and an expert in the manpower field. He has been a frequent adviser to the federal government since 1948.

In a letter to employees of the Department of Health, Education and Welfare, Secretary Wilbur J. Cohen, who will return to teaching at the University of Michigan, listed 13 health goals for the 1970s. He previously had said that his teaching position would leave him time to work for new and expanded health programs.

Most of the goals are noncontroversial, and Cohen did not elaborate on details of implementation where controversy arises. The goals include:

• Continued expansion of medical research and more rapid dissemination of new knowledge to prevent and cure illness. • Elimination of economic barriers to medical care, through comprehensive health insurance and other public and private programs. • Major reduction in infant mortality and early childhood diseases. • Elimination of malnutrition. • Improvement in the organization and delivery of medical care, with continued emphasis on high quality. • Widespread transplantation of human organs and development of artificial organs. • Expanded prevention and improved chances of recovery from heart disease, stroke, and cancer. • Increase of health manpower and better use of professional skills. • Elimination of large mental institutions and expansion of community mental health centers accessible to all. • Family planning services available to everyone. • Improvement in the quality of the environment, with major reduction in air and water pollution. • Reduction of alcoholism, drug addiction, mental illness and mental retardation, and accidents. • Elimination of smallpox, diphtheria, polio, whooping cough, and measles.

*** *** ***

Developments in the drug field include starts on tests of an old drug in treatment of pneumonia and a new one for Parkinson's disease.

The National Institutes of Health started a wide-spread test of a polyvalent pneumoncoccal vaccine that was discarded 20 years ago with the entrance of antibiotics. Edwin M. Lerner, MD, coordinator of the test program, said it had been demonstrated that persons die of pneumonia because of early stage damage and that antibiotics have not been a cure-all. The old vaccine, manufactured by E. R. Squibb and Sons, was licensed and found effective in 1948, but was taken off the market in 1952 because of lack of sales.

"Penicillin was the cure-all in those days," Dr. Lerner said. "It was felt that there was no need to vaccinate people. After all, we thought we could cure them."

The Public Health Service announced a program to test an experimental drug in treatment of Parkinson's disease. Robert Q. Marston, MD, Director of the National Institutes of Health said the drug, L-DOPA, may help "up to 75% of patients." But he cautioned it has "serious and unpleasant side effects" which must be carefully checked.

Other developments in the drug field included:

• The Pharmaceutical Manufacturers Association disputed the finding of an HEW Task Force on Drugs that a $41.7 million saving could have been obtained by use of generic instead of brand name products in 67 of the 409 prescription drugs used most often by elderly persons. C. Joseph Stetler, PMA president, said the claim was not documented and was based "on the unproven assumption that prescriptions written by generic name cost substantially less."

• A Food and Drug Administration Advisory Committee said that existing data on whether birth control pills can cause cancer of the cervix is still inconclusive. The Advisory Committee on Obstetrics and Gynecology repeated the recommendation of the World Health Organization that all women using birth control pills undergo 6-to-12 month medical examinations.

• The government has drawn up a national drug system to permit computerized processing of drug data. The code is designed to provide the needed

common language in which to communicate rapidly and accurately essential information about drugs. The code was drawn up by HEW and the Drug Trade Conference, which represents drug manufacturers and distributors.

Regional Medical programs, a majority involving continuing education of physicians, are now underway in 24 areas, with 261 separate projects being carried out, according to a government report.

Thirty-one regions have not yet embarked on specific programs.

States and regions with the most listed projects to date are Tennessee (mid-South), 27; Missouri, 25; Texas, 24; South Carolina, 16; Intermountain (Utah, Wyoming, Montana, Idaho, Nevada), 16; Michigan, 15; Georgia, 14; Kansas, 14; Washington-Alaska, 4; Albany (N. Y.), 10; Memphis (Tenn.), 10; California, 9; Rochester, (N. Y.), 9; and Oregon, 7.

The nation's largest mental institution, Saint Elizabeth Hospital, Washington, D. C., will be converted to a model of modern mental health services, training, and research by the National Institute of Mental Health.

The National Center for Mental Health Services training and research will be headed by Sherman N. Kieffer, MD, Assistant Surgeon General of USPHS.

The new national center will have three divisions. One is the Saint Elizabeth Hospital-Division of Clinical and Community Services. In collaboration with the D. C. Department of Health, this division will operate the area D Community Mental Health Center which includes much of Southeast Washington. It will also provide active treatment, care and rehabilitation services for the beneficiaries of Saint Elizabeth.

A division of intramural training, will administer an expanded institute program to train new types of auxiliary mental health manpower and to test new training techniques.

The third division will be responsible for the development of new approaches in clinical research.

2 Minutes Away—at 752-5400

porting to a District of Columbia Medical Society meeting, said he also found "moderate" to "severe" flaws in chromosomes of "at least 50%" of 75 female LSD users. The flaws are in genetic material and could impair offspring, he said.

Jacobson and his associates said they found their subjects by advertising in an underground newspaper for pregnant LSD users, "No Questions Asked." Among the group he has studied, he said, there were 22 normal births and 35 abortions, only 14 of which produced fetuses intact enough for study.

Four of the 14 had a disease called "exencephaly" which normally shows in less than one-half of 1% of babies, he said. It is fatal, he said. One characteristic is that the brain is completely outside the skull.

Eighty per cent of the women studied were unmarried, Jacobson's aides said. Some had taken as little as one dose of LSD and others had taken it numerous times.

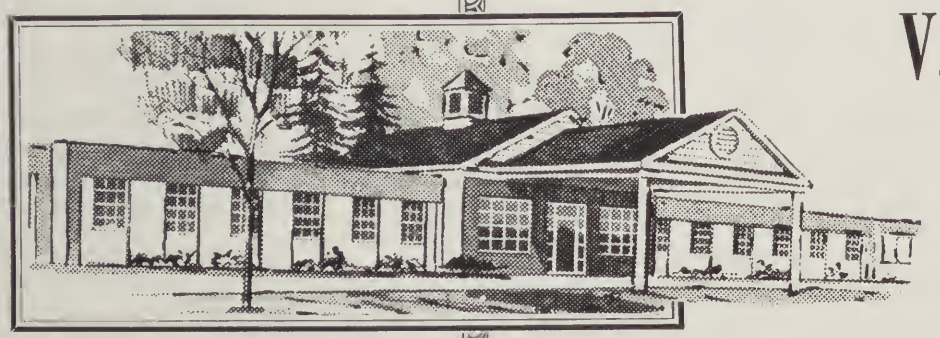
Man is threatened with self-destruction because he has damaged, ignored and contaminated "the earth that gives him life," according to a federal government official.

Charles C. Johnson, Jr., Administrator of the newly created Consumer Protection and Environmental Health Service in the Department of Health, Education and Welfare, said the threat from pollution, unsafe food, drugs, water and chemical additives to food—among other things—is increasing each year.

Johnson spoke at a symposium on Human Ecology. Ecology is the branch of science dealing with the relationship between people and their environment.

"With regard to the physical environment, we have reached, or at the very least are rapidly approaching, a critical point," Johnson told the gathering of scientists, lawyers, sociologists, engineers and other specialists.

"Every year, pollution gets worse, rather than better; the threat from unsafe food, drugs, water and a variety of consumer products is increasing; the quality of American life, particularly urban life, is deteriorating in a morass of environmental problems so complex as to appear almost beyond remedy," Johnson said.



★ This extended care Nursing Home is Approved by the Joint Commission on Accreditation of Hospitals

★ One story new fire-safe construction.

★ No steps, ramps or elevators needed.

★ Inspection invited. Reasonable rates.

★ All facilities available to private physicians.

★ Professional Total Care Program

★ Continuous Physical Rehabilitation by registered therapists in specially equipped department.

MRS. HARRY L. BERMAN, EDITOR

woman's auxiliary

Workshops

Six State Auxiliary Chairmen returned from attending Regional Workshops in Boston on October 17-18 full of enthusiasm and information to impart to their County Chairmen in "mini-sessions" at Med-Chi, following a Board Meeting on October 30th. They were Mrs. Elmer G. Linhardt, Education Research Fund; Mrs. Wallace A. Sadowsky, Membership; Mrs. George S. Malouf, Safety and Disaster Preparedness; Mrs. G. Allen Moulton, Community Health Services; Mrs. Robert J. Dawson, Health Careers; and Mrs. H. Leonard Warres who substituted for Mrs. William C. Brewer, Mental Health. All were deeply impressed by the lectures, group discussions and intense periods of instruction.

Mrs. Elmer G. Linhardt learned of an amazing number of fund-raising projects and gleaned a vast amount of material in the two-day session. She was furnished with detailed information relative to ERF Contributions to medical schools, Bio-medical Research Institute and Student Loans. She reported on other state-level projects and ventures related to fund-raising which had proved highly successful.

Mrs. Warres brought back numerous suggestions for programs and activities in Mental Health which included education, service, program-planning and fund-raising. Discussions were many-faceted on unmet needs and services available in emotional and mental illnesses. Movies are available to illustrate the pitfalls of narcotic addiction, suicide prevention and the mistreatment of young children. The movies and talks, professionally produced and financed by auxiliary groups, can be distributed to high schools, youth groups and religious centers as are those dealing with Health Careers on which Mrs. Dawson reported to her County Health Careers Chairmen. In that area the talks and movies were designed to call attention to the many fascinating medical and paramedical professions and foster interest in them.

Mrs. Moulton was advised on assessing the most needed health services in the community. "Friendly visitors," meals for shut-ins, homemakers and health aides were examples of areas where support was offered by the medical auxiliaries.

Mrs. Malouf dispensed material and advice on how to handle situations in many kinds of emergencies, including a training course for babysitters, Block Mothers to aid troubled children enroute to and from school, poison prevention and preparedness for disaster.

Mrs. Sadowsky, working in the field of membership and programming, stressed the importance of planning interesting meetings with emphasis on stimulating programs to enlarge membership attendance and meet the health-related needs of each community.

County Workshops

Harford County Auxiliary continues to support the Center for the Retarded and plans are underway for a residential unit.

Washington County Auxiliary has had gratifying results in presenting National's Package Program "Mental Health of Children." PTAs from twenty-three elementary schools have requested it to date.

MEDICAL NEWS

Liam Haim, MD, of Silver Spring has been elected a Fellow-Elect of the American College of Obstetricians and Gynecologists.

* * *

The *Dictionary of International Biography,* Fifth Edition, 1968-1969, has included **Kenneth W. Taber, MD,** of Churchville, in its biographical listing.

D.I.B. is a record of contemporary achievement and is distributed in 112 countries. The Fifth Edition contains more than 14,000 biographical sketches.

Dr. Taber was cited for his distinguished career as physician and surgeon. His main field of interest is radiology.

* * *

The American Academy of Pediatrics has urged that health insurance plans provide more comprehensive coverage for the delivery of medical services to infants and children. Spokesmen for the Academy recently stated that a major portion of child health care is not covered by health insurance.

The AAP statement defined comprehensive pediatric care as "all services given to infants, children and adolescents necessary to establish and maintain optimal health.

"When indicated, these services should be rendered on a 24-hour basis by a personal physician or his aid acting under the physician's supervision either in the office, hospital outpatient department, or other facility."

* * *

The Baltimore Academy of Surgery was recently established to promote high standards in the profession and provide a forum for scientific discussion.

George D. Zuidema, MD, director of the department of surgery at The Johns Hopkins School of Medicine, has been elected president of the 51-member organization.

The Academy held its first scientific discussion in November and plans to hold at least two more meetings before June.

The formation of the group is the culmination of over a year's effort by **George G. Finney, Sr., MD,** former chief of surgery at Union Memorial Hospital, and **George H. Yeager, MD,** medical director of the University of Maryland Hospital.

Other officers of the Academy include: **Arnold M. Seligman, MD, vice president; John N. Classen, MD, secretary; T. Brannon Hubbard, Jr., MD, treasurer; Karl F. Mech, MD, recorder; and Richard W. Steenburg, MD, program chairman.**

* * *

Sheila C. Mitchell, MD, has been named Assistant to the Director, National Heart Institute.

In her new post, Dr. Mitchell will participate in, administer, and coordinate NHI collaborative studies and targeted research activities in congenital and rheumatic heart disease. She will also serve as executive secretary for the NHI Executive Committee and for special review panels and as project officer for a training contract with the Board of Pediatric Cardiology to evaluate testing and training procedures in the congenital heart disease field.

* * *

Since the inception of the AMA Volunteer Physicians for Viet Nam, July 1, 1965, ten Maryland physicians have volunteered to spend at least 60 days in provincial hospitals, supplementing drastically inadequate resident medical staffs.

From Baltimore, the volunteers include **Michael B. Flynn, MD, Stephen M. Nagy, Jr., MD, Thomas H. Powell, MD, Glendon E. Rayson, MD, and Donald K. Wallace, MD.**

Robert E. Eby, MD, Olney; **Louis Padovano, MD,** Woodstock; and **Patrick A. Reardon, MD,** Seabrook, are the others from the state.

Both Dr. Padovano and Dr. Powell volunteered for a second tour of duty.

* * *

Karim F. Rashad, MD, of Baltimore, was recented named a Diplomate of the American Board of Anesthesiology.

* * *

The following physicians will serve on the **Committee on Medical Practice of The Professional Forum** through 1970: **William E. Gilmore, MD, Chairman; Fred N. Cole, MD, vice chairman, Thoracic Surgery; Newland E. Day, MD, vice chairman, Internal Medicine; Joseph H. Hooper,**

Jr., MD, vice chairman, Surgery; Raymond L. Markley, Jr., MD, vice chairman, Gynecology; Robert McFadden, MD, assistant vice chairman, Surgery; Alfred G. Ossman, Jr., MD, assistant vice chairman, Medicine; John M. Rehberger, MD, vice chairman, Otolaryngology; Douglas H. Stone, MD, assistant vice chairman, Surgery (on leave of absence); Henry L. Wollenweber, MD, vice chairman, Pathology.

Selected to serve on the **Committee on Dental Practice** are **Paul S. Keller, DDS, chairman,** and **Conrad L. Inman, Jr., DDS, vice chairman.**

Officers of The Professional Forum are **J. E. Rytten, president; Newland E. Day, MD, vice president,** and **Howard E. DeMuth, Jr., secretary-treasurer.** Mr. Rytten is a criminologist and Mr. DeMuth is an attorney.

Mr. John Sargeant will continue to serve the Committee on Medical Practice as liaison officer between the Forum and county, state and national medical associations.

* * *

Harry M. Robinson, Jr., MD, professor and head of the division of dermatology at the University of Maryland School of Medicine, has been awarded a three-year, $300,000 grant from the Vocational Rehabilitation Administration to establish a special regional facility for rehabilitation applied to dermatology—the first of its kind anywhere in the world.

Very few of the general rehabilitation centers ever accept patients unable to work because of chronic skin trouble, Dr. Robinson stated. According to a recent survey, 76% of such centers in the United States and Canada report they do not admit patients whose primary cause of disability is dermatosis. This creates an unfortunate situation for a worker suffering from a skin eruption caused or aggravated by substances he handles on his job, because he may be incapacitated for a much longer period of time than a person who breaks a leg as the result of an industrial injury.

Many chronic skin patients do draw Workman's Compensation benefits and in Maryland, during fiscal year 1963, 68% of the nonfatal claims that the Medical Board for Occupational Disease reviewed and allowed without contest involved workmen with occupational dermatosis.

Dr. Robinson's primary objective is to study rehabilitation problems presented by patients with various skin problems, and to establish a multidisciplinary program for the management of those problems.

"Early diagnosis and prompt referral for rehabilitation are the key to success," Dr. Robinson said. "Obviously, not all patients are suitable candidates for rehabilitation, but prolonged delay may mean loss of motivation. Medical care, vocational guidance, and rehabilitation can all be carried out at the same time. Our ultimate goal is to restore the injured or handicapped to useful and productive life."

Dr. Robinson is recruiting staff now for the new facility, which will be located on the second floor of Howard Hall, near the present Rehabilitation Unit.

* * *

Robert M. Heyssel, MD, has been named director of the outpatient services at The Johns Hopkins Hospital, a position vacant since **John C. Harvey, MD,** left the post last January 1 to become medical director of the new Good Samaritan Hospital.

Dr. Heyssel, who is also associate professor of medicine and associate dean for health care programs for The Johns Hopkins University School of Medicine, will be administratively responsible for the development and operation of the hospital's outpatient care programs. As director of a hospital department, he will serve as a member of the medical board.

Before joining The Hopkins staff in May, Dr. Heyssel served for nine years, most recently as associate professor of medicine, on the faculty of Vanderbilt University School of Medicine.

At Vanderbilt he also was director of the department of medicine's division of nuclear medicine and biophysics, and director of the Vanderbilt University Hospital radioisotope center.

As a result of his research, Dr. Heyssel was first to describe the dose-response relationship of radiation to human leukemia in a nonselected large population. He also did the first large scale study of absorption of Vitamin B12 from natural foods, and made the first reasonably based estimates of minimal daily dietary requirements for Vitamin B12.

He also has done research on iron metabolism, blood platelets and health care systems.

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

No two women are quite alike...

and no other oral contraceptive is quite like Ovulen-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

The progestin is distinctive, and for some women this may mean a different clinical response. The Compack® tablet dispenser is distinctive; its functional simplicity makes it virtually patient-proof. The acceptance of Ovulen-21 is distinctive... together with Ovulen®, it is more often prescribed than any other individual contraceptive product currently available.

Indication—Oral contraception.

Contraindications—Thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia, undiagnosed abnormal genital bleeding.

Warnings—Watch for the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism, retinal thrombosis); if present or suspected discontinue the drug immediately.

British studies reported in April 1968[1,2] estimate there is a seven- to tenfold increase in mortality and morbidity due to thromboembolic diseases in women taking oral contraceptives. In these controlled retrospective studies, involving 36 reported deaths and 58 hospitalizations due to "idiopathic" thromboembolism, statistical evaluation indicated that the differences observed between users and non-users were highly significant. The conclusions reached in the studies are summarized in the table below:

Comparison of Mortality and Hospitalization Rates Due to Thromboembolic Disease in Users and Non-Users of Oral Contraceptives in Britain.

Category	Mortality Rates		Hospitalization Rates (Morbidity)
	Age 20-34	Age 35-44	Age 20-44
Users of Oral Contraceptives	1.5/100,000	3.9/100,000	47/100,000
Non-Users	0.2/100,000	0.5/100,000	5/100,000

No comparable studies are yet available in the United States. The British data, especially as they indicate the magnitude of the increased risk to the individual patient, cannot be applied directly to women in other countries in which the incidences of spontaneously occurring thromboembolic disease may differ.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or sudden onset of proptosis, diplopia or migraine. Withdraw medication if papilledema or retinal vascular lesions are found.

Since the safety of Ovulen in pregnancy has not been demonstrated, it is recommended that pregnancy be ruled out for any patient who has missed two consecutive periods before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the first missed period.

A small fraction of the hormone agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—Pretreatment physical examination should include special reference to the breasts and pelvic organs, and a Papanicolaou smear.

Endocrine and possibly liver function tests may be affected by Ovulen. Therefore, it is recommended that such tests if abnormal be repeated after the drug has been withdrawn for two months.

Pre-existing uterine fibromyomas may increase in size under the influence of progestogen-estrogen preparations.

Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation.

In breakthrough bleeding, and all irregular vaginal bleeding, consider nonfunctional causes. Adequate diagnostic measures are indicated in undiagnosed vaginal bleeding.

Carefully observe patients with a history of psychic depression and discontinue the drug if severe depression recurs.

Any possible influence of prolonged Ovulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study.

A decrease in glucose tolerance has occurred in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be observed carefully while receiving Ovulen.

Because of the effects of estrogens on epiphyseal closure Ovulen should be used judiciously in young patients in whom bone growth is not complete.

The age of the patient constitutes no absolute limiting factor, although Ovulen therapy may mask the onset of the climacteric.

The pathologist should be informed of Ovulen therapy when relevant specimens are submitted.

Adverse Reactions—A statistically significant association has been shown between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: cerebrovascular accidents, neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement, secretion), change in weight, changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, allergic rash, rise in blood pressure in susceptible individuals, mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme and nodosum, hemorrhagic eruption, itching.

The following laboratory results may be altered by oral contraceptives: hepatic function: increased sulfobromophthalein and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T^3 uptake values; metyrapone test; pregnanediol determination.

SEARLE Where "The Pill" Began
G. D. SEARLE & CO., P. O. Box 5110, Chicago, Illinois 60680

Help clear up that miserable stuffed-up feeling with Dimetapp. Each hard-working Extentab brings welcome relief from the stuffiness, drip and congestion of upper respiratory conditions for up to 10-12 hours. Yet, patients seldom experience drowsiness or overstimulation. The key to success is the Dimetapp formula: Dimetane (brompheniramine maleate)—along with phenylephrine and phenylpropanolamine, two time-tested decongestants. They get the job done... in a hurry.

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripher vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thromb cytopenia, have been reported on rare occasions. Drowsiness, lassitud nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

So he'll breathe easier:

relieve anxiety while you relieve pain.

Relief of pain is usually a major goal in traumatic conditions. But often of importance, too, is alleviation of anxiety and tension that may heighten patient discomfort.

Single-prescription, non-narcotic Equagesic may effectively relieve pain. *And* ease anxiety and tension.

TABLETS

Equagesic®

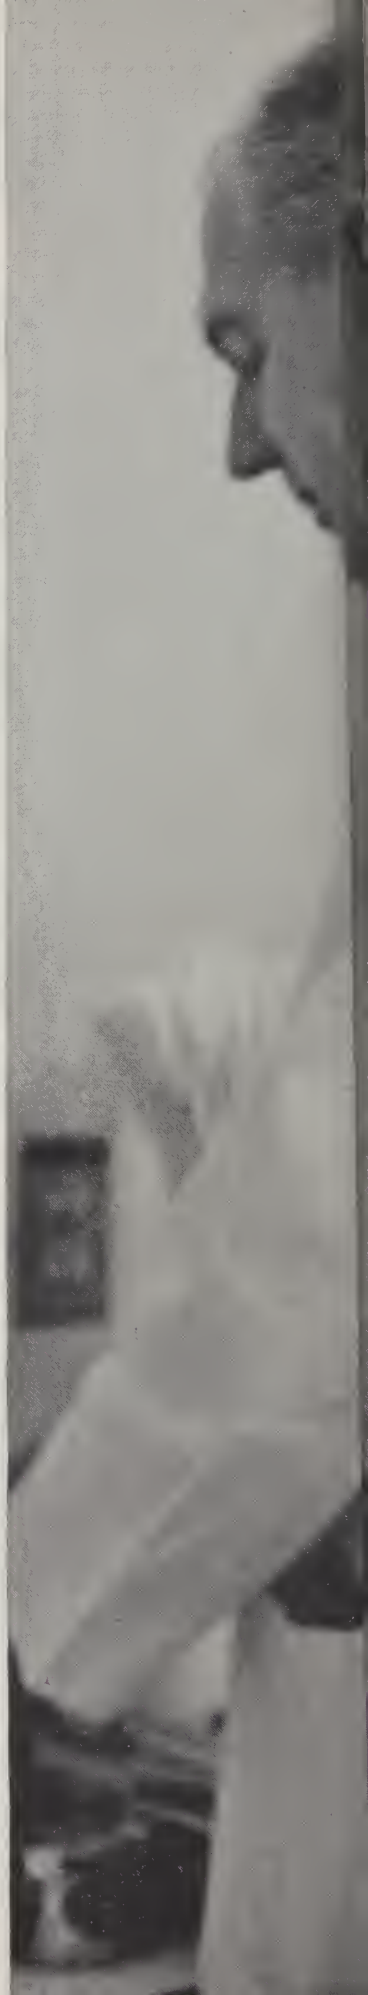
(meprobamate and ethoheptazine citrate with aspirin) Wyeth®

IN BRIEF.

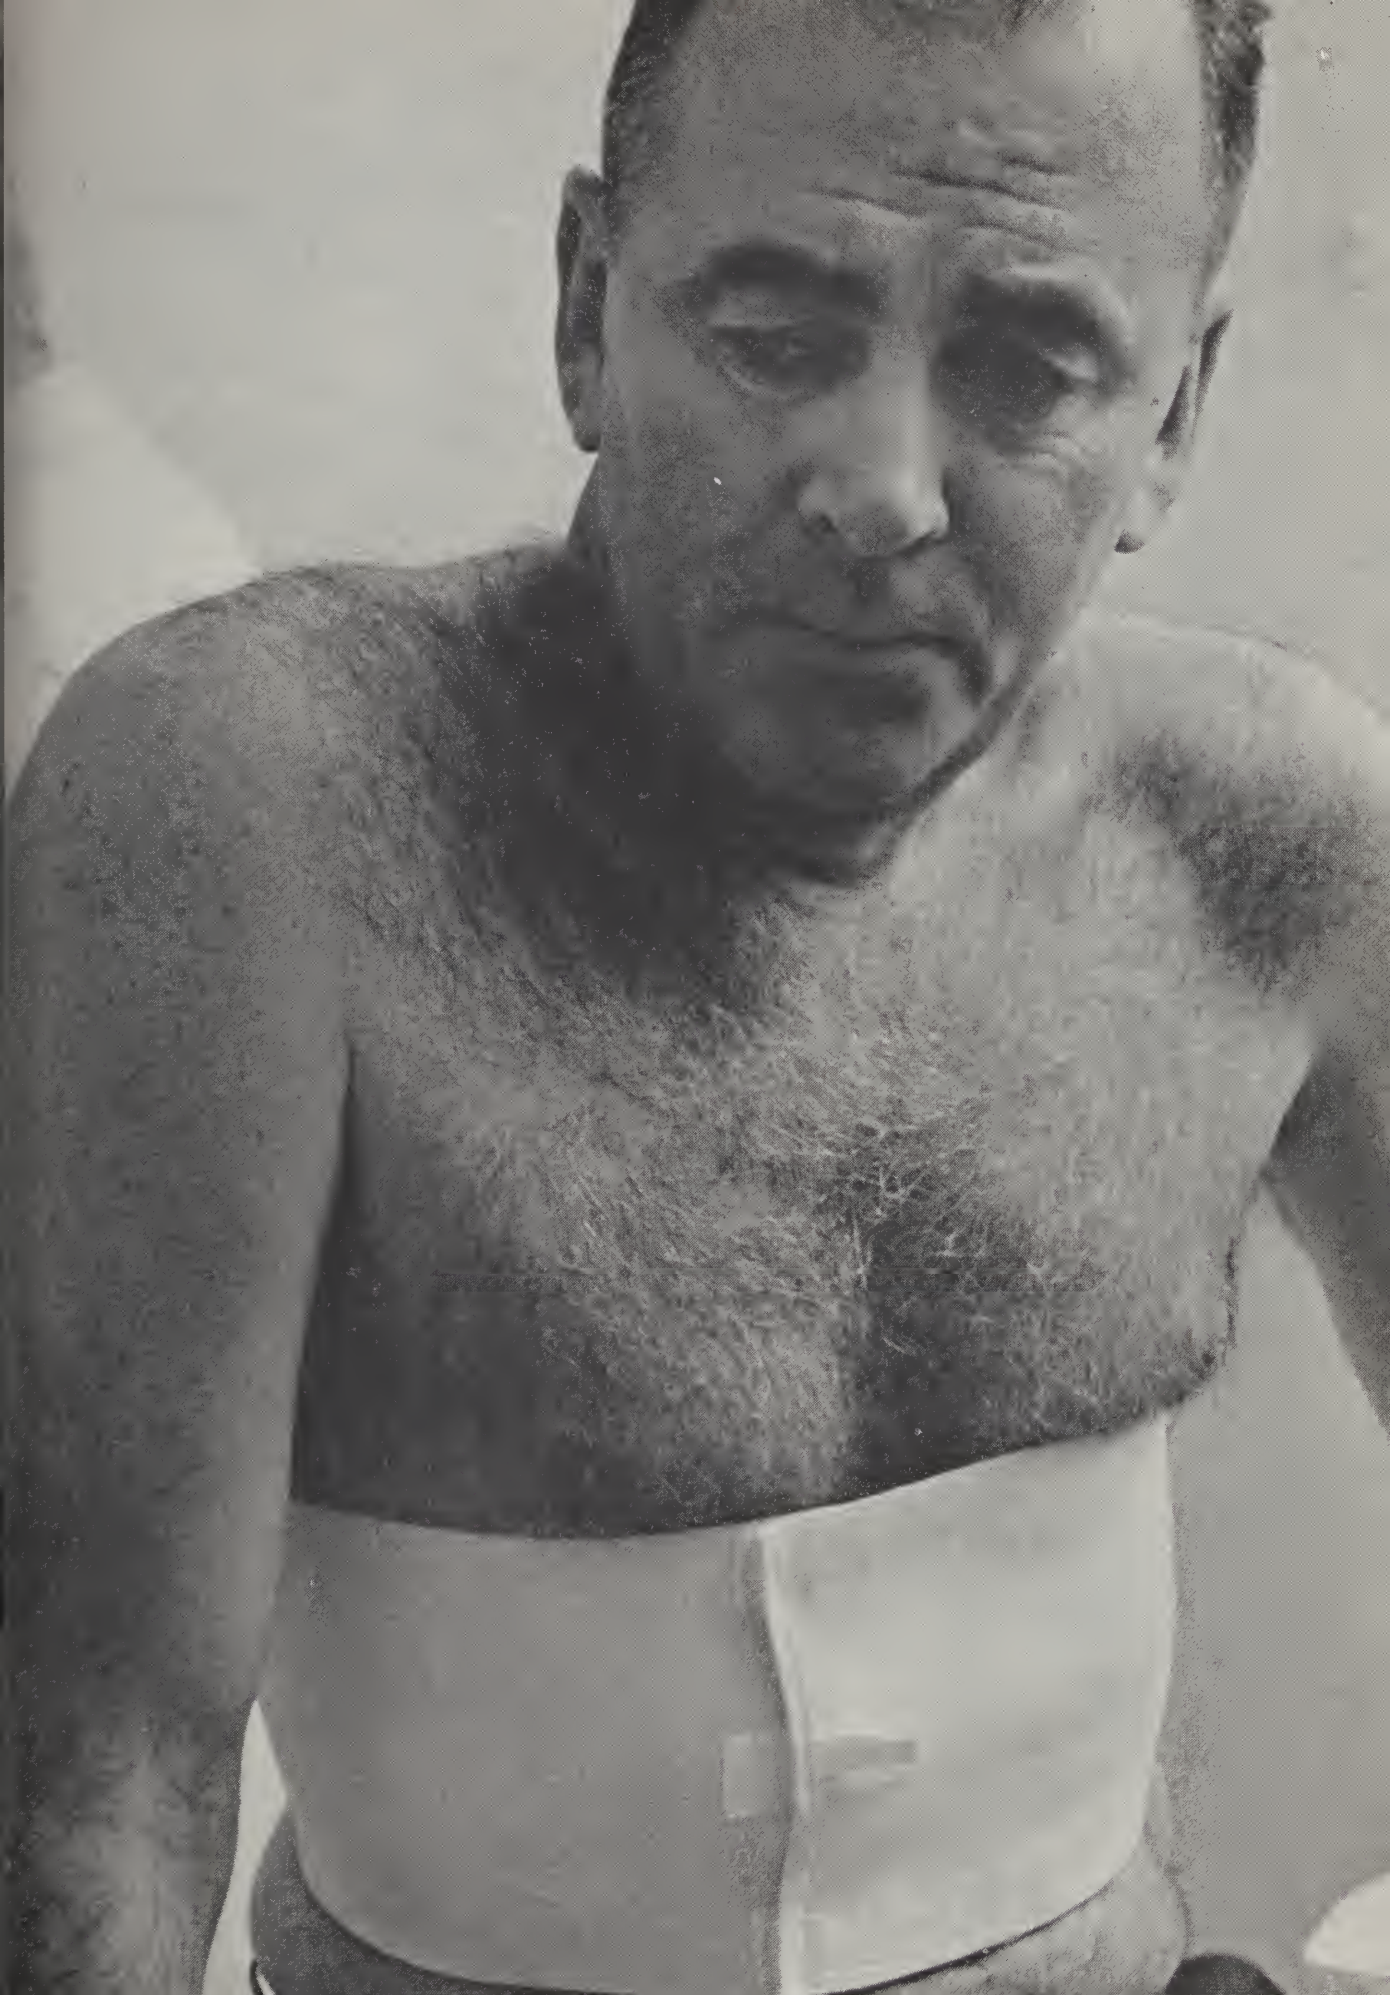
Contraindications: History of sensitivity or severe intolerance to aspirin, meprobamate or ethoheptazine citrate.

Warnings: USE IN PREGNANCY: Safety for use during pregnancy or lactation has not been established; therefore, it should be used in pregnant patients or women of child-bearing age only when the physician judges its use essential to the patient's welfare.

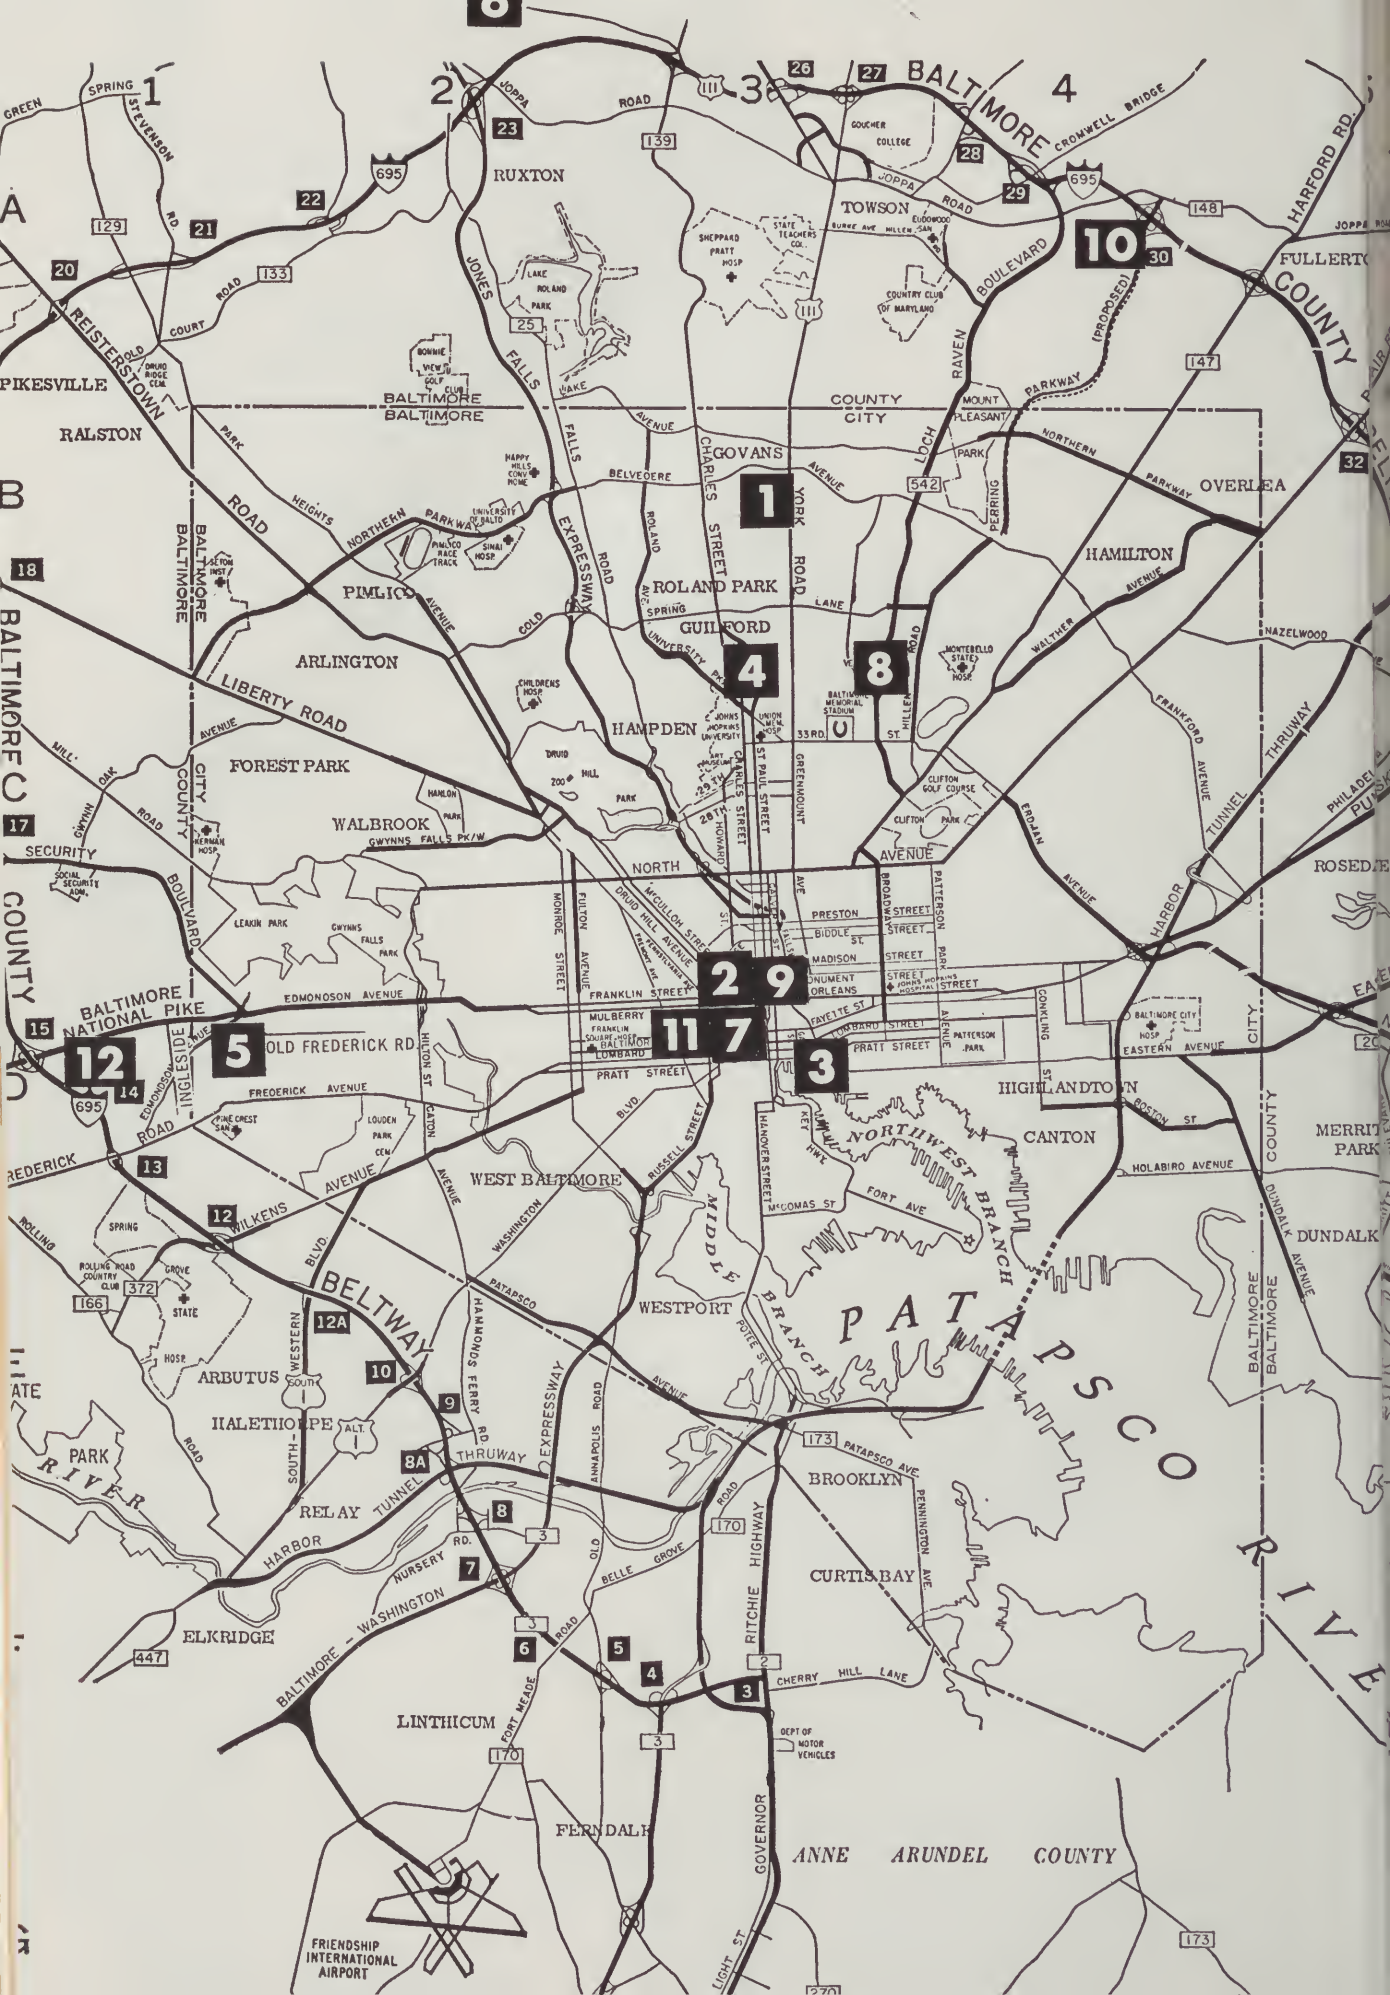
Precautions: Keep out of reach of children. Not recommended for patients 12 years old or less. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate in susceptible persons—as alcoholics, ex-addicts, severe psychoneurotics—has resulted in dependence or habituation. Withdraw gradually after prolonged excessive dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance, with resultant slowed reactions and impaired judgment and coordination. If drowsiness, ataxia or visual disturbances (impairment of accommodation and visual acuity) occur, reduce dose. If symptoms persist, patients should not operate machinery or drive. After meprobamate overdose, prompt sleep, reduction of blood pressure, pulse and respiratory rates to basal levels, and hyperventilation are reported. Give cautiously and in small amounts to patients with suicidal tendencies. Treat attempted suicide (has resulted in coma, shock, vasomotor and respiratory collapse and anuria) with gastric lavage and appropriate symptomatic therapy (CNS stimulants and pressor amines as indicated). Two instances of accidental or intentional significant overdosage with ethoheptazine and aspirin have been reported. These were accompanied by CNS depression (drowsiness and lightheadedness) but resulted in uneventful recovery. On basis of pharmacologic data, CNS stimulation could be anticipated, with nausea, vomiting and salicylate intoxication (requires induced vomiting or gastric lavage, specific parenteral electrolyte therapy for ketoacidosis and dehydration, and observation for hypoprothrombinemic hemorrhage [usually requires whole blood transfusions]).



Adverse Reactions: Ethoheptazine and aspirin may cause nausea with or without vomiting and epigastric distress, in a small percentage of patients. Dizziness is rare at recommended dosage. Meprobamate may cause drowsiness, ataxia and rarely allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses. Such patients may have had no previous contact with meprobamate and may or may not have an allergic history. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. If allergic reaction occurs, discontinue meprobamate; do not reinstitute. Severe reactions, observed very rarely, include fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. These cases should be treated symptomatically including, when indicated, such medication as epinephrine, antihistamine and possibly hydrocortisone. A few cases of leukopenia, usually transient, have been reported on continuous use. Rarely, aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported, almost always in presence of known toxic agents.



Overdosage: See precautions section for management of overdosage.



Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.

When Should A Physician Assist the Surgeon?

When is it obligatory that an operating surgeon have a physician assistant present and scrubbed at the operating table?

The Joint Commission on Accreditation of Hospitals stipulates that there must be a physician assistant present "in any procedure with unusual hazard to life." The American College of Surgeons, as a member of the JCAH, supports this as a minimum requirement. The determination of what constitutes "unusual hazard" rests therefore with the conscience of the operating surgeon and is part of his responsibility to his patient, but the surgeon must be prepared to defend his decision before the medical staff and the governing body of his hospital.

Ideally, perhaps there should always be a competent surgeon backing up the operator during every surgical procedure in the event of an unanticipated accident to the latter. Such sudden incapacities must be rare indeed and their potentiality can not be compared with the necessity for a co-pilot of a plane. There are frequent circumstances when it is clearly not feasible to have a second surgeon, or even a physician assistant, on the operating team. Moreover, there are simple procedures at which it would be superfluous to insist upon a physician assistant.

The problem is where to draw the line, and the delineation must be made by the conscience of the surgeon. It is fatuous to propose, as certain medico-legal experts and even state licensing bodies have recently done, that there should be a physician assistant at every "major surgical operation." This begs the question. No group of surgeons has ever been able to agree upon a definition of "major" versus "minor" surgical procedures. The truth is that the degree of hazard of an operation lies not so much in the nature of the procedure itself as in the age, obesity, condition, etc. of the patient. These are the factors which the operating surgeon must evaluate in each case and which will determine what constitutes adequate assistance.

Adolescence:

A Prominent "Disease" of the '60s

A subject that cuts across almost all fields of medicine is adolescence. The problems —emotional and medical—which confront the adolescent of the 1960's are not unique. In fact, they are as old as civilization itself. The big difference today seems to lie in the fact that these problems are more talked about, more publicized by all media, and possibly more criticized than ever before.

And then again, teen-agers have achieved a more prominent position in our social structure—by virtue of their number—and instead of concealing any behavior patterns which seem to deviate from the accepted norm, they blatantly announce them to the world. Today, with the hippie and yippie elements invading and destroying the once-solid family institution, wholesale sex is bragged about. Pregnant teen-agers don't try to hide their condition. Some even appear proud that they are about to become unwed mothers.

Despite the misplaced emphasis on deviate behavior during this decade, this is a major problem which the Adolescent Medical Center of Sinai Hospital is attempting to cope with. The AMC is divided into several sections—one deals with psychiatric problems, another with obstetrics, and another aspect is the Family Life Service. Although the center is still in its infancy, the results seem promising.

It is not necessarily a sex-oriented center but one cannot deny that most adolescent problems are created by a sex vs. morality conflict.

The purpose of the center is to provide a place where adolescents—boys and girls—can go for counseling, group discussion and therapy, if necessary. The teen-agers gather in their respective peer groups, thus insuring their uninhibited participation.

According to Herbert L. Yousem, MD, Director of the Family OB Clinic at the Center, aside from the definite group of retarded children referred to the center, "the remainder of the group has a normal intelligence and they are just actor-outers so to speak."

The following papers were presented during a meeting of the Baltimore City Medical Society on February 2, 1968, Zamoiski Auditorium, Sinai Hospital of Baltimore, Inc.

EMOTIONAL PROBLEMS OF ADOLESCENCE

"Youth is disintegrating. The youngsters of the land have a disrespect for their elders, and a contempt for authority in every form. Vandalism is rife and crime of all kinds is rampant among our young people. The Nation is in peril."

—Unknown Egyptian priest
4,000 years ago

"Our youth now loves luxury. They have bad manners and contempt for authority. They show disrespect for their elders and love idle chatter in place of exercise. Children are now tyrants—not the servants of the household. They no longer rise when elders enter the room. They contradict their parents, chatter before company, gobble up their food, and tyrannize their teachers."

—Socrates
About 400 B.C.E.
—2,300 years ago

The reader is familiar with the anatomical, physiological, hormonal changes in adolescence and the concomitant psychological changes and conflicts.

This paper will deal with some of the psychosocial aspects of adolescence: the struggle between the drive for independence and the prolonged economic dependence; sexual drives and moral restriction; professed moral codes and practiced adult behavior; emergence from youth into adulthood and the search for identity; choice of career, conflict over immediate gratification of some desires versus postponement of hedonistic satisfaction for supposed greater satisfaction following prolonged education with its concomitant restriction of freedom, independence and reduction of self-esteem as a "not yet adult."

These conflicts lead to confusion and resentment toward the adult world which is blamed on one hand for causing much of the confusion and on the other hand for not providing the assistance and guidance for solving these conflicts. This resentment may lead to rebellion—and rebellion at times may manifest itself in the form of delinquent behavior. Delinquency, however, is not a problem of our generation; it has always been present to greater or lesser degrees and in a variety of forms.

Some of the peculiarities of *this* generation's adolescent problems, how they may differ from the last generation's and may be specific for our times are important items for us to consider. I do not want to imply that they are greater in value, in degree, in severity, or in depth *now* than they were in earlier years. I only want to draw attention to the differences and to factors which may be specific for the events in the 1960's.

Dependency vs. Independency

Longer *dependency* as a result of longer education needed in preparation for life in our technological society is a fact. At the same time we find more sophistication and knowledge in all fields of human endeavor at an earlier age since scientific, political, military, sociological and even personal events such as marriage, divorce, litigations and crimes of known personalities are spread with amazing rapidity through the news media and need little effort on the part of the individual to acquire. No longer is it necessary to read through newspapers and journals to acquire information and news from all over the world; it can be obtained, without reading ability, through radio or T.V., and even the most disinterested child is exposed to this information. This worldly knowledge, plus the ready availability of transportation, not only by car but also over long distances by plane, produce a sense of quasi-independence and a temptation toward using this available opportunity. Yet economically the dependency period has been prolonged, and those who hold the purse strings exert control, even if professing to allow freedom. The son who hears "you make your own decisions" knows that if father wants to stop him, all he has to do is pull the purse strings closed.

The physician's contribution can be anticipatory counseling for young parents to avoid prolonged suppressive child rearing practices in earlier childhood, and instead train the child to assume gradually a more self-reliant attitude and thus avoid his need for rebellion.

Sexual Problems

The sexual conflicts of the adolescent are well known. He is driven by organ and hormone development as well as curiosity to prove and test his virility, but he is restricted by moral rules.

Confusion and further conflict are added to ever-existing sexual conflicts of the adolescent by changing mores and the changing role of the woman. These changes are already accepted as *modus vivendi* by a large part of adolescent society, both male and female, but not by all, and certainly not by the majority of the parental generation. The great emphasis on and use of sex by the advertising and entertainment industry provides constant visual and auditory sexual stimulation. Often slanted, exaggerated and sensationalized news reporting of items, which only a generation ago would have been whispered only as gossip, constantly remind the child even long before he enters his teens of the blatant discrepancy between professed rules to live by and actual adult behavior. I am very glad to hear that educators are beginning to offer a family-life education program which will include a broader-based sex education. Our past efforts have been rendered ineffective by starting too late, saying too little, avoiding the real issues, and not allowing the child to react to what is presented.

The physician has a role here, not only by offering sex education to the individual patient when he is requested to do so and as he sees the need, but also by counseling the parents and impressing on them the need for a broad, early, and honest clarification. Since many parents are reluctant or unable to discuss this subject, parental education either directly or through literature or a combination of both is often a first step. Active support of the school program and participation in such a program is a further contribution the physician can make.

Parental Unavailability Plus Shrinking Family

The family structure has changed over the last decades with grandparents, aunts and uncles removed from the nuclear family and being of only limited availability to the children. Even the role of the maid has changed from the live-in maid, at times serving over two generations and almost a part of the family, to the once-a-week, ever-changing cleaning woman. I wonder just how significant the presence or absence of such a family servant in the house has been or is in many families. I have never seen a study about this subject but am convinced that its psychological significance is great and that many maids have made a greater impact upon the child than his socially active, absent mother.

Paternal absence or unavailability is again well known, and many a doctor is guilty of contributing to this social phenomenon. Often more traumatic than the physical absence is the emotional distance of the father who, even when present, buries himself in the newspaper or stares at T.V. Little is gained if both child and father watch T.V. or sit at sports events, hardly noticing each other's presence. Emotional and intellectual inter-

action is necessary to fulfill the paternal role.

Early counseling may influence some parents to arrange some part of their time so as to benefit the child for whom they profess to be willing to give everything. Often this "everything" is meant to be material goods only and does not include one's own time and affection.

Affluence

The almost unlimited availability of recreational facilities and material goods in many circles, not only among the wealthiest, and the emphasis on pleasure and luxury are evidently not enough to fill a young person's life.

To develop self-esteem, to feel like a person in his own right, to be somebody with pride in himself, to prove himself, a person must have a challenge, a task to achieve, a goal to reach. The young person, whose identity is not yet established and whose personality is not formed, is even more in need of this opportunity than the adult who can look back at past achievements or challenges he has met and whose need for new ones is less acute.

If we meet all needs, protect him from all dangers, prevent his mistakes or correct them for him we deprive the child of the opportunity to establish the identity which all persons need.

The youngster who makes a mistake and then corrects it, is wiser and prouder than the one whose mistake has been prevented by his mother and who has been made to feel infantile and incapable through this benevolent and yet really damaging protective act.

Mobility

Mobility from one geographic location to another has increased and the reasons are manyfold. Some such moves are unavoidable, some are desirable from one angle and undesirable from another, and some seem unjustified. What we physicians can do at times is to point out some effects which the move may have upon the various family members, and of which the parents may not be aware.

A known environment gives a feeling of security, even identity. Moving to the periphery of the city may mean isolation, transportation difficulties and increased dependency, separation from friends, different living standards and, of course, unfamiliar surroundings with regard to physical structures and persons.

Antisocial acts are more difficult to perpetrate towards friends, or friends of the family, while the "new kid," not yet accepted by the established clan, may find it easy to act out against people or property which he considers strange or even hostile.

I do not want to give the impression that delinquent behavior has its origin in a single cause, or even that uprooting, mobility and nonacceptance are major causes, but they are significant. Yielding to status pressure, advertising temptations and real or imagined social factors should be weighed in the light of the social and psychological impact a move has upon each family member. The physician may be the person who is familiar enough with the social structure of the community to give some guidance.

Scholastic Problems

Motivation toward longer education is often counteracted by immature wishes for early tangible results. Can the immature adolescent postpone the gratification of his dreams—constantly reinforced by advertisements and the affluent image of friends and neighbors? His parents often have achieved success, especially in the business world, without the formal education now deemed necessary for success. They, therefore, do not serve as an example. They also offer a standard of living which the child could only achieve after considerable education and delay. Early marriage and offspring again may create the conflict between "needs now" and "opportunities later." Is he willing to prolong his dependency upon his parents in order to achieve similar standards on his own strength, or does he want his own car *now* while partaking of his parents' comfort, only to find out years later that he is neither prepared to achieve these standards nor to give them up?

Push for College in Various Social Strata

Children in *lower socio-economic* groups have few examples of higher education in their midst. Anti-educational influence by peers who strive and succeed in immediately gratifying their needs with such visible results as a car, clothes and available cash for entertainment is strong. Most youngsters do not appreciate that these pleasures represent only a false sense of independence since the child's income can satisfy these hedonistic desires only while having food, shelter and medical needs provided by parents. Parents who on

one hand allow and support this freedom and on the other hand use their financial and factual control to limit the independence create a conflictual situation between themselves and the child.

The push for a college education in the *higher socio-economic* group for children lacking the intellectual qualifications for college work creates frustration and disappointment to parents and embarrassment over competitive failures with peers and siblings. From an early age the child is told, "You are no good unless you go to college," and is pushed toward certain categories of jobs requiring intellectual faculties which he may not have.

The old-fashioned way of starting at the bottom of the ladder and working one's way up, depending on ability and willingness to expend effort, is no longer accepted. Inappropriate study and career choice often leads to failure because of limited ability or motivation to take on the greater responsibility and expenditure of energy which the higher job requires. Backtracking and assuming a lower level, educationally or occupationally, is more difficult and traumatic to one's self-esteem than stopping at a comfortable level of ascent. The family physician can be of great service to the child by showing his interest in scholastic achievement and, in case of possible conflict, by urging the child to seek educational and vocational guidance.

The adolescent in rebellion may find the educational aims of his parents the most vulnerable areas to rebel against. His conscious desire to comply and to get the education the parents have outlined for him and the job which would meet his and his parents' desire is counteracted by resentment that this would not be *his* spontaneous decision but only compliance and submission to parental wishes and a further certificate of his powerless, dependent position.

Problems of Identity

The adolescent has left childhood and not yet entered adult society. He looks for his niche there and tries to find his position and the image he likes to see himself in when grown up. He is constantly questioning the established rules, laws, and customs and observing adult behavior. What he sees is not always very encouraging; in fact his criticism may be shared by a significant part of the adult society, and thus revolutionary movements or subcultures such as the hippies are born.

Summary

Most adolescents find the solution to the above conflicts through discussions with peers, parents, teachers, counselors, adults available through sports, social or political associations and through books. For them the problems are transient; they are the growing pains of the maturing process. For others, the problems and their solutions take on a more serious aspect.

Those who cannot find the solution or clarification they seek and cannot tolerate to live in a conflictual and often contradictory world may suffer from lack of self-respect and self-confidence, get depressed and even suicidal. The incidence of suicide and suicidal attempt is increasing, especially in the college population. The physician, whether as family physician or school or college physician or perhaps as neighbor and friend, can offer a helping hand. The key to this assistance is open communication between adolescent and some significant adult person. Problems may become particularly threatening if communication is lacking at home. Fathers are often busy in more than one job or in pleasurable and social activities and may never have established meaningful communication with their sons. Mothers, either equally busy or bewildered by the complexity of problems and disappointed that the husband doesn't play the role of father adequately, may be unable or unwilling to supply the needs of the adolescent. This may be especially true for the male adolescent who may not want to share his problem with a woman, in whose eyes the woman has not achieved equal status and is still considered educationally and intellectually inferior—a hangover from earlier decades. The female-headed household, so common in the inner-city population, presents this problem frequently and in grave form. Whether the community-centered pediatric and mental health facilities will be able to assist these youngsters will depend to a great extent on whether they will have the support of other agencies, such as the Big Brother League, sports organizations, Scouts, and Recreational Centers with adequate male staffing.

The physician can help by being alert to emotional problems, by an early recognition of self-depreciation, mood swings, periods of depression in the adolescent, and by making himself available for counseling or therapy or by arranging appropriate referrals.

THE MEDICAL PROBLEMS OF THE ADOLESCENT

MATTHEW DEBUSKEY, MD
Associate Professor of Pediatrics
The Johns Hopkins University School of Medicine;
Participating Pediatrician, Adolescent Center
The Sinai Hospital of Baltimore, Inc.

The metamorphosis of youth, transforming the child into a healthy and reasonably adjusted adult, is one of the most critical stages in the natural history of man. This period, adolescence, has focused the concern of societies throughout historical ages and legendary epochs. Initiation rites of ancient as well as contemporary primitive tribes, and the Eleusinian mysteries of the cultured Greeks, attest to the apprehension with which adults viewed the transformation of puberty, and the ceremonial indoctrination with which they enveloped it.

Our own social order has not solved the trials of this transition. The many sociological and technological changes, with which we are still struggling to accommodate, have compelled a prolongation of that interval. No longer is it condensed into a relatively constricted season of sexual maturation, but it extends through the entire teen-age span, and vaguely beyond. Meanwhile, it is generating a force—volatile, impulsive—that from time to time tests the fabric of our own cultural heritage.

The trend in medicine is to emphasize comprehensive care. This concept of the "total" patient assumes a preventative, as well as a therapeutic posture toward both organic and psychological aspects of his well-being. Physicians, despite their physical and treatment orientation are slowly moving in this direction. No one merits this approach more than the adolescent, who so blithely tangles these ingredients with almost impish abandon, and who, in a world of confusion, catapults with coiled power toward a veiled and mobile goal.

Our society is exhibiting a marked and justifiable concern about youth. Fifty percent of our population is under 25 years of age. Approximately 33,000,000 compose the teen-age bracket. Floods of articles, predominantly dealing with psychological dysfunction and social maladaptation, appearing in both popular and professional publications, tax our understanding and fog our judgment. At the meeting of the American Orthopsychiatric Association, 15 meetings referable to adolescence were scheduled; more time than was assigned to any other single topic. Yet with the exception of a few physicians, Gallagher in Boston, Heald in Washington, Johnson in Detroit, and

of a few topics, growth, stature and sexual maturation, there has existed no particularly general effort to explore the variations of organic disorders in the adolescent; nor any concerted attempt to systematically organize this body of knowledge.

At this point, I freely express my belief, that for the individual as well as for the community, the most important single facet, among the many faces of adolescence, is his emotional adjustment. Yet to minimize the organic aspect of his development is negligence, and is unwarranted. What early signals to predictably serious future medical conditions can be identified here? Where are we to focus our efforts for cure or amelioration? What are the most lethal or crippling conditions at this age?

Some clue to the answer of this last question can be obtained from the Vital Statistics published by the U.S. Department of Health, Education and Welfare. Table I lists the figures for 1962.

TABLE I

NATIONAL CENTER HEALTH STATISTICS DEPT. H.E.W.

Deaths In 1962	Total	Male	Female
10-19 YEARS	20,448	13,897	6,551
NON-VIOLENT	10,042		
Neoplasms	2,219		
Cardiovascular Renal	1,297		
1) Vascular Lesions C.N.S.	317		
2) Heart	578		
3) Rheum. Fever & Chronic Rheumatic Heart Disease	279		
4) Chronic Nephritis	266		
Congenital Anomalies	910		
Influenza & Pneumonia	720		
Infectious Diseases Excluding Pneumonia	497		
Diabetes	143		
Asthma	87		
VIOLENT DEATHS	10,426	8,179	2,247
Motor Vehicles	6,278	4,701	1,577
Suicide	658	498	160
Homicide	664	460	204

We notice that violent deaths are more common than non-violent ones. The motor vehicle, by far, is the single largest cause of death. If we are sincere in our determination to reduce adolescent mortality, this might be the area where we exercise whatever influence we possess.

"Reported" suicides almost equal the combined total of rheumatic heart disease, chronic nephritis, diabetes and asthma. If the estimated figure of 1,000 suicides a year occurring among our college students alone, as was proposed by a recent conference of university authorities, is accepted, then it exceeds by far this collected total.

A brief glance at the more recent 1964 statistics is even more depressing. In that year, out of a total of 22,900 deaths, violence provided 13,700; motor vehicles, 7,400; suicide, 743. The three or four to one ratio of male to female is arresting. Why our boy has to prove his virility by killing himself will be a fascinating thesis for future anthropologists. In each of the non-violent categories listed, concentrated effort is being devoted to the study of its development and management. Our big problem in this area is the distribution and provision of service. But these are mortality tables. When we attempt to ascertain morbidity rates and tendencies, we meet with even greater difficulty. There is a paucity of reviews separating adolescents from either children or adults. Yet with the striking changes in biochemical and hormonal systems that occur at this stage, it would be useful to inquire what medical conditions are:

1) initiated (e.g., acne, pregnancy)
2) terminated (m. audouini)
3) potentiated (hypertension)
4) attenuated (petit mal, rheumatic fever)

and why?

However, we might have more information in the years immediately ahead, because very rapidly throughout the country, new clinics are being established for the care of youth. In Baltimore, adolescent services are expanding. Some ten years ago St. Agnes opened an inpatient section, and Sinai simultaneously, an outpatient clinic that has proceeded in a most unexpected and much heralded direction. City, G.B.M.C. and others are allotting bed space for separate units. Hopkins is developing an exemplary training and service program that has earned tremendous intramural popularity. With ideal cooperation, the Department of Medicine and the Department of Pediatrics have assigned an intern, a resident and an attending physician from each service to function simultaneously in this unit, established on C.M.S.C.-9. Introduced in July 1966, it has grown from a small service to a census currently of 18-20 medical patients. It has a very active

educational and recreational program directed by the Child Life Department, and receives patients by referral, by private admission, and from the clinics.

Garell[1] has compiled reports from 225 hospitals, that responded to a circular inquiry.

55 of these have adolescent services,
16 have clinics,
24 have wards,
13 have combined services.

Most of these are small. Some inpatient care is motivated by expediency. The preponderant number of clinics operate one day a week, with an appointment schedule, and rarely see acute or exacerbated chronic ailments. Generalizations from their data are dubious.

However, he has collected the five most frequent diagnoses of emotional disorders, and organic diseases, made in 19 clinics, and has rated them in diminishing order of frequency.

Among **emotional disorders** the first five were:

1) **adjustment reaction to adolescence (10 clinics, the most frequent diagnosis)**
2) **behavior problems**
3) **personality and trait disorders**
4) **psychoneurotic reactions**
5) **scholastic failure**

Each clinic has its own idiosyncrasies in labeling conditions.

Among **organic disorders,** the most frequent were:

1) **obesity (10, most frequent diagnosis)**
2) **acne (1)**
3) **allergy**
4) **seizures**
5) **orthopedic problems**
6) **infectious diseases**
7) **menstrual disorders**
8) **mental retardation**
9) **growth and metabolic disorders**
10) **normal adolescent**

The list, obviously non-representative of a cross-section of adolescent care, with obesity and acne leading the series, and normalcy at the bottom, indicates either referrals from frustrated physicians or problems that tormented the patient himself.

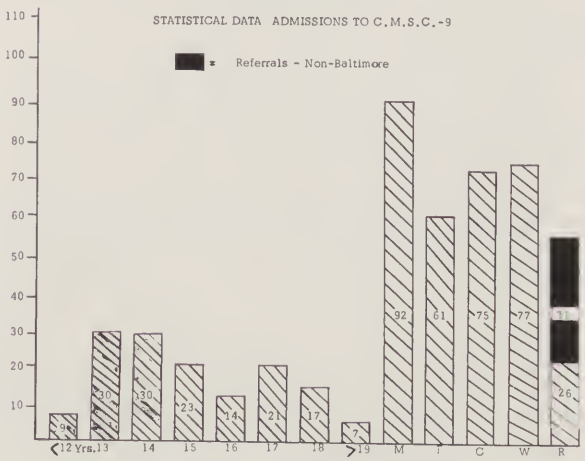
Perhaps a study by Sklar and Downs[2] would be interesting to review. They surveyed all the adolescent diagnoses made by an emergency room service, operating 24 hours a day at a hospital that served a rather stable community of 270,000 people. Teen-agers represented 10% of the population and one-fifth were presumed to use the hospital as its primary medical resource. There occurred 1,172 visits in one year. This formed about 10% of the total registrants.

Accidents and acts of violence produced 51.7% of the total; illnesses and non-traumatic incidents 48.3%. These figures, interestingly, closely resemble the national mortality statistics.

Eighty percent of the visits for surgical services were to treat lacerations, fractures, burns, concussions, etc. Appendicitis was diagnosed 15 times.

Medically, 68% of care was for gastroenteritis and U.R.I. Diagnoses of asthma, hepatitis and communicable disease were rare.

Twelve percent of the ob-gyn problems centered on pregnancy. Six of eight children between 13-16 years had been raped. Menstrual complaints were uncommon.



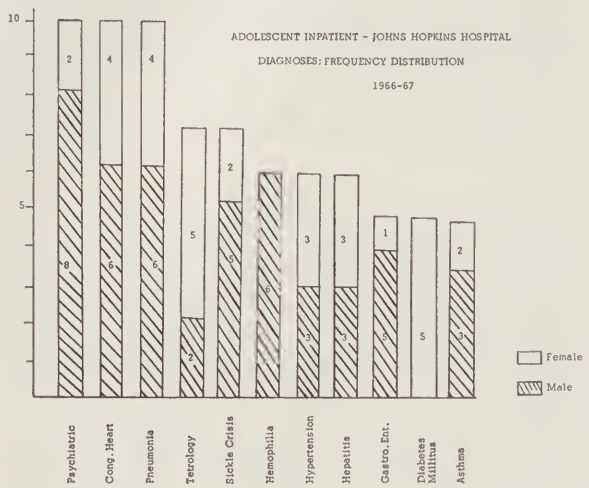
Thirty-three percent of psychiatric patients were suicidal attempts. Only three drug addicts were seen.

Here, obviously, once again the emphasis is on trauma and violence.

Finally, for inpatient care, I have reviewed the case histories of 153 medical patients admitted to the adolescent floor of the Children's Medical and Surgical Center at Hopkins from July 1966 to July 1967.

As you can see from Table II, there were more admissions in the lower age scale. Possibly this group requires more hospitalization. Possibly the generalist and the internist are not yet aware of the existence of this program.

TABLE II



The extreme age levels reveal that there does not exist a compulsive rigidity about limitations to "teens".

Finally, the "R" represents referrals. This would inject a bias in any prevalence figures that could be determined.

Table III rates, in diminishing order, the frequency of diagnostic categories. The psychiatric group was placed first to demonstrate that despite our preliminary intention to avoid admission of emotional problems, these will inevitably appear in any adolescent group, in the guise of conversion, hysteria, psychosomatic and seizure phenomena.

TABLE III

A very active division of cardiology heavily influences the number of congenital hearts as well as that of tetralogy.

Pneumonia was the third item, sharing top position. Surprisingly, most of these were of bacterial origin.

Sickle cell crisis was undiminished. Two of these were of the aplastic variety.

Hemophiliac problems were unabated. It was the 20th admission of one child.

Hypertension should be a fascinating problem to explore at this age. It might be more instructive if we could jettison the magic adult numbers of 140/90. The causes in these patients were well distributed over the entire etiological range: hypoplastic kidney, chronic nephritis, thyrotoxicosis, systemic lupus, coarctation and finally that puzzling state of "labile vascular system."

Masland,[3] in a three-year experience with 1,795 patients, found 25 patients with blood pressure over 140/90. This represented an incidence of 1.4%—only seven of these were organic, three resulting from coarctation.

Hepatitis: two of these were chronic and four acute. One patient had received gamma globulin prophylactically after an exposure two months prior to admission.

Diabetics were admitted because of difficulty in management. One was insulin resistant, requiring over 200 units of insulin for a period of time. This male-female ratio will be interesting to watch.

Two of the asthmatics were particularly handicapped by psychoneurotic states.

Freeman,[4] in an allergic survey of 8th and 12th grade children in Denver, reported that 82% of 130 children, who had asthma as the sole manifestation of atopy before ten years of age, were either improved or well at puberty. Few cases receded after 13 years.

In Table IV, three of the patients with iron deficiency anemia were admitted for other primary conditions. Nevertheless, there has been evidence to suggest that many young college women will exhaust their meager iron stores with one pregnancy. I think many of our adolescents are operating on a tight iron economy.

TABLE IV

**ADOLESCENT INPATIENT—
JOHNS HOPKINS HOSPITAL
DIAGNOSES; FREQUENCY DISTRIBUTION
1966-67**

	TOTAL	M	F
IRON DEFICIENCY	4	1	3
MENINGITIS ASEPTIC	4	3	1
SARCOIDOSIS	4	4	0
RHEUMATIC HEART (1 ACUTE)	4	2	2
BACTERIAL ENDOCARDITIS	2	1	1
SUPRAVENTRICULAR PAROXYSMAL TACHYCARDIA	2	0	2
TUBERCULOSIS	3	1	2
SYPHILIS ACQUIRED (SECONDARY)	2	2	0
SUICIDE ATTEMPT (DRUG)	2	1	1
THYROTOXICOSIS	2	0	2

The pediatricians were surprised to recognize sarcoidosis at such an incidence. These were primarily pulmonary. Two were confirmed by liver biopsy and one by scalene node.

Three of the rheumatic hearts were chronic; only one was acute. This is consistent with the

assumption that acute rheumatic fever declines at puberty.

Tuberculosis is certainly a continuing risk. One patient had pleurisy; one cervical nodes; and one, early dissemination.

Syphilis, acquired, both primary and active secondary stages, is a new disease for pediatricians. Following a post World War II drop in incidence, syphilis is again rising sharply and is occurring with unprecedented frequency in adolescents. One of our patients was admitted as nephrosis. Greater recourse to the VDRL and complete retraction of the foreskin, will net more youngsters in early stages of the disease. The negligence of the physician in reporting these cases, enables contacts, innocently if not naively, to explosively disseminate the infection. This is a serious public health problem.

One suicidal effort was straightforward barbiturate ingestion. The other was dicoumarin and presented quite a bizarre picture.

This last table, Table V, records single cases. I am displaying them because in my own previous experience they are far more important than their low rating here justifies. Some are, by preference, ambulatory problems; others, however, are not; as our total study population rises we will be able to estimate their statistical significance.

TABLE V

ADDITIONAL DIAGNOSES

OBESITY
MIGRAINE
PEPTIC ULCER
ULCERATIVE COLITIS
REGIONAL ENTERITIS
CHOLELITHIASIS
ORTHOSTATIC ALBUMINURIA
METROMENORRHAGIA
DYSMENORRHEA
ATOPIC ECZEMA
EPIPHYSITIS
PSEUDOTUMOR CEREBRI

Obesity, as we observed previously, is a most weighty adolescent problem. With increasing knowledge of lipid metabolism and developing laboratory techniques, we might find some metabolic explanation for this derangement. It is ironic that with undernutrition such a crucial global problem, our major example of malnutrition should be adiposity. I am sure that in many instances, a psychological factor is of cardinal significance.

At this age both migraine and peptic ulcer are ceasing to masquerade in odd garb and are assuming the more characteristic symptom complex of the adult.

We are seeing in children an increasing number of neighboring intestinal conditions, overlapping would be more appropriate, Crohn's disease and ulcerative colitis. Possibly the paucity here might be attributed to our clientele.

Cholelithiasis, not associated with hemoglobinopathy, is rare in childhood, but if we increase our index of suspicion, we'll begin to identify more cases in teen-agers.

The diagnosis of orthostatic albuminuria is diminishing. With kidney biopsies, relatively safe and certainly more common, morphological changes are being reported in this condition; a sanguine attitude might no longer be appropriate.

Gynecological conditions are seen in the gynob clinic and hospitalization, I presume, is made to their own units, unfortunately.

Epiphysitis is not rare, its etiology is controversial, and it is generally out-patient oriented. The child studied had Scheuermann's disease, an involvement of the vertebral bodies.

Pseudotumor cerebri is an uncommon, but not unique, condition of the adolescent girl. It is alarming until diagnosis is confirmed, but then generally responds nicely to active therapy.

This then is a presentation of the organic medical status of adolescence. Each varied approach will produce variations in statistics. Yet in treating an individual child, statistics are not that vital. However, irrefragably, the one most livid fact revealed, is the devastating carnage, in death and mutilation, that violence wreaks among these kids.

A COMPREHENSIVE APPROACH TO OBSTETRICAL PROBLEMS OF ADOLESCENCE

The obstetrical and pediatric departments at Sinai recognized that the adolescent girl with her gynecologic and obstetrical problems benefited from an approach which recognized that she was different. Her gynecological problems were puzzling to her, her pregnancy was more threatening to her, her pregnancy problems more divergent than those of her elders and consequently more severe.

The development of the primary sex glands and secondary sex characteristics also cast a shadow on feelings and attitudes of the adolescent. The development of these glands results in concentration on specific sexual feelings and activities which differentiate the adolescent from the younger child.

Children who approach adolescence with attitudes and taboos as a result of personal inhibitions and/or environmental rigidity in respect to sex topics are thrown into intense conflict. The resolution of this conflict is generally handled either through direct rebellion against parental and environmental standards or in flight from the reality conflict. Both horns of the dilemma assert themselves and the adolescent either talks through sex, may act through sex, or may flee from the problem by idealizing the opposite sex.

In sharp contrast to the idealized object of sexual fantasy is the stark reality of menstruation, masturbation, and nocturnal emission. Unless reasonably prepared for these natural functions, most children have sharp conflicts about these processes, but the normal adolescent after puberty is able to shift the emphasis from the pure and unadulterated general satisfaction to other aspects of the sex drive which have more points of contact with his total self-interest and goals. The resulting socialization with the same or opposite sex is as a rule associated with a letup in the acute and overwhelming need for masturbation. Little by little the sex life takes its place as one in the mosaic of functions constituting the activity of the person.

The less fortunate child finds greater difficulty in developing a well integrated mode of reaction. The aggressive child runs into social difficulties while the sensitive child withdraws from the

situation into himself. With this process occurring in the adolescent and with approximately 30% of our population being adolescents, is there any surprise to the 1960's being labeled the decade of the sexual revolution?

But something else is happening in the 1960's. Concern about inadequacies in the health and welfare services available to the American public has risen. These considerations prompted the establishment of an Adolescent Center at Sinai Hospital.

A problem of considerable importance amongst adolescents is that of pregnancy. For the past five years over 1000 girls, 14-16 years of age have given birth to live infants each year in the city of Baltimore. Taking into account losses due to spontaneous and induced abortion and fetal death, the number of pregnancies in this age group is considerably higher. Unplanned and undesired juvenile pregnancies thus constitute a serious socio-medical problem for this community and in effect presents a major "chronic illness" of adolescent girls.

In the young adolescent, pregnancy has been variously reported to be associated with higher incidences of toxemias, contracted pelvis, prolonged labor. Among the offspring of such pregnancies there is the excess of prematurity and of neonatal and early childhood death. However little is known of the long-term outcome in regard to later morbidity of the offspring of the adolescent mother. In addition the question may be raised as to the adequacy of the mother-child relationship which develops when the mother is of such a young age.

A significant educational liability commonly results from adolescent pregnancies. In most urban areas pregnancy represents an abrupt end to the young person's education. Although in many instances she is permitted to return to school after delivery, very often problems of care of the infant as well as the basic difficulty of adjustment prevent her from actually continuing her education. Although in cities such as Baltimore the establishment of schools for pregnant teenagers has tended to improve the situation, the problem has by no means been eliminated. Termination of a girl's schooling all too often represents the end of her vocational training as well. In many instances such girls become permanently dependent upon public assistance.

Once a teen-ager has had an illegitimate child there is a strong likelihood that she will have one or more other illegitimate children within the next several years. In essence, these girls continue to repeat a cyclical pattern from one generation to the next of dependence upon public support and of pregnancy at a very young age. The likelihood of their becoming self-supporting or of moving up the socio-economic scale is indeed slim.

In our experience, the pregnant teen-ager frequently has an unrealistic hope that the putative father will marry her. All too often however, teen-age illegitimate pregnancy represents the beginning of a one-parent family. When marriage does result it is frequently of an unstable nature and it has been observed that two to three out of every four teen-age marriages end in divorce.

As a result of these significant obstetrical and neonatal problems, as well as the serious social and educational difficulties associated with adolescent pregnancy, a Family OB Clinic was instituted at the Sinai Hospital Adolescent Center. Here the chief residents in the specialty, an attending physician, a social worker, and a public health nurse join forces in this special clinic to try to minimize these problems by providing the pregnant adolescent with prenatal care and later with postpartum care and birth control.

These patients meet in a special night clinic where all the patients are their own age and facing similar problems. There are no adult patients in the environment. A more personal approach to the problem is effected because of the stability of the clinic personnel. The chief resident acts as her clinic physician as well as her hospital physician at the time of labor and delivery whenever feasible. In this manner a closer doctor-patient relationship develops with a freer exchange of communication between the two. Problems are more easily brought up and discussed by the adolescent with the physician. The public health nurse is involved with the patient during the clinic sessions, at the patient's home both before and after delivery, as well as while the patient is in the hospital. Likewise the social worker is involved with the patient from the first visit in attempting to solve the multiple social problems such as school, marriage, support, physical facilities for the baby, etc.

All are basically geared towards solving the special medical problems involved, towards keeping the patient in school during and after the

pregnancy, and of assuring adequate neonatal and pediatric care to the newborn.

Data from this program is still being analyzed. It is hoped that this multi-disciplined approach will have results comparable to those of Yale and Syracuse where the children did return to school, did bring their babies back to the doctor for care, and did show improvements in toxemia rates, cesarean section rates, and in general seemed to fare much better as a result of this type of plan.

However, regardless of how well motivated and sensitive the services for pregnant teen-agers are, many of the tragic consequences of unplanned and undesired pregnancies in the adolescent cannot be prevented. These problems therefore warrant an attempt at primary prevention of adolescent pregnancy. It is a reality of the present-day situation that in many instances moral teaching and parental sanction are not sufficient to prevent teen-agers from engaging in sexual activity. With this realization therefore the provision of birth control information and services on a limited and selected scale were instituted at the Sinai Adolescent Center in a special program known as the Adolescent Family Life Service. This service provides birth control information and service for sexually active nulliparous teen-agers with the consent of the teen-ager and her parents.

This clinic is manned by a pediatrician, gynecologist, social worker, and public health nurse. Their services are supplemented by those of a clinical psychologist and psychiatrist when indicated. The patients are referred to the clinic primarily by the public health nurses and social workers in the field and from various community agencies. At the time of referral, the adolescent and her parents have individual screening interviews. If mutually agreeing, the child is then seen in the Adolescent Center per se where a complete history, physical, and laboratory workup are performed. Appropriate contraception is then dispensed and a close followup of the patient is made by means of frequent clinic visits and public health nurse home visits.

During clinic visits the girl participates in group discussions about any topic the group elects to talk about that night, such as parental relationships, school problems, sex, pregnancy, boys, etc.

In our first year, 93 girls were screened and only 62 accepted by the clinic. Of these, 43 have been placed on contraception and 30 of them have been maintained on contraception for more than one year with no pregnancies resulting. The remaining children have been referred to various counseling services, specialty clinics, or other resources. As you can see, the numbers are too small to evaluate the effectiveness of this program but we are continuing to collect relevant data as our clinic grows.

It nonetheless should be clear that premarital pregnancies cannot be controlled by devices alone. Clearly, attitudes have to change also. Many females cannot use a diaphragm or take the pill because they do not conceive of themselves as always being prepared for coitus. They must be emotionally carried away for intercourse to occur. Such a self-image is permanent and blocks the use of many contraceptive devices. A fuller solution to the problems requires a deeper attitudinal change regarding the acceptability or non-acceptability of premarital coitus. It is in this area that the close doctor-patient relationship, the nurse-patient relationship, the social worker-patient relationship which exists in this clinic has its bearing on the problem. Likewise the group discussion sessions assist in developing these attitudes.

A major problem has arisen in these sessions with dealing with family-life teaching and sex education. It has proven difficult to find suitable audiovisual material and other teaching aids for low socio-economic groups particularly among the non-white adolescents. There is an urgent need for developing appropriate material in this area.

Some fear that this program may encourage promiscuity. One may question this latter view because the available evidence indicates that it is one's basic values and the pressure of the situation that actually determine whether intercourse takes place. The knowledge and availability of effective contraception may be a minor factor in such a decision but it would rarely be a determining force. The best contraceptively informed youths are not necessarily the most permissive.

In summary, we have described the adolescent period as a turbulent one. Medical concern about this age group is rising. Obstetrics and gynecology together with pediatrics has an intimate role to play in resolving these problems.

The Council met on November 14, 1968, and took the following actions:

1. Adopted financial statements, both operating and dedicated fund, through September 30, 1968.
2. Approved recommendations for Emeritus Membership from component societies to be submitted to the House of Delegates.
3. Approved an increase in financial aid to the family of an ill physician; and approved refunding 1968 dues to the same family.
4. Approved installation of protective grillwork for the History of Medicine collection in the library.
5. Adopted a School Health Examination Form, with the urgent request that emphasis be placed on the completion of Part I of the form by parents before requesting the physician to complete Part II.
6. Adopted 1969 Council meeting dates.
7. Presented a second Viet Nam plaque to Louis Padovano, MD, of Woodstock, Md.
8. Authorized employment of legal counsel for 1969.
9. Authorized the writing of a letter requesting active Faculty participation as a full partner in the Regional Medical Program.
10. Ratified various legal defense cases.
11. Declined with regret the granting of legal defense in one case because of late payment of dues.
12. Heard of the conclusion of various legal defense cases.
13. Directed the Faculty office to ascertain if malpractice insurers would pay "punitive" damages if awarded in professional liability cases.
14. Authorized changing the location of the 1969 Semiannual meeting to Hershey, Pa.
15. Authorized continued discussions by a special Ad Hoc Committee in connection with a proposed Multiphasic Screening program.

ETHICS CORNER

Use of Credit Cards

From time to time, the Faculty Office receives requests for information with respect to physicians utilizing the services of Credit Card Companies. Recently, the Bank America Credit Card group raised the question as to the ethics of use of their cards by physicians.

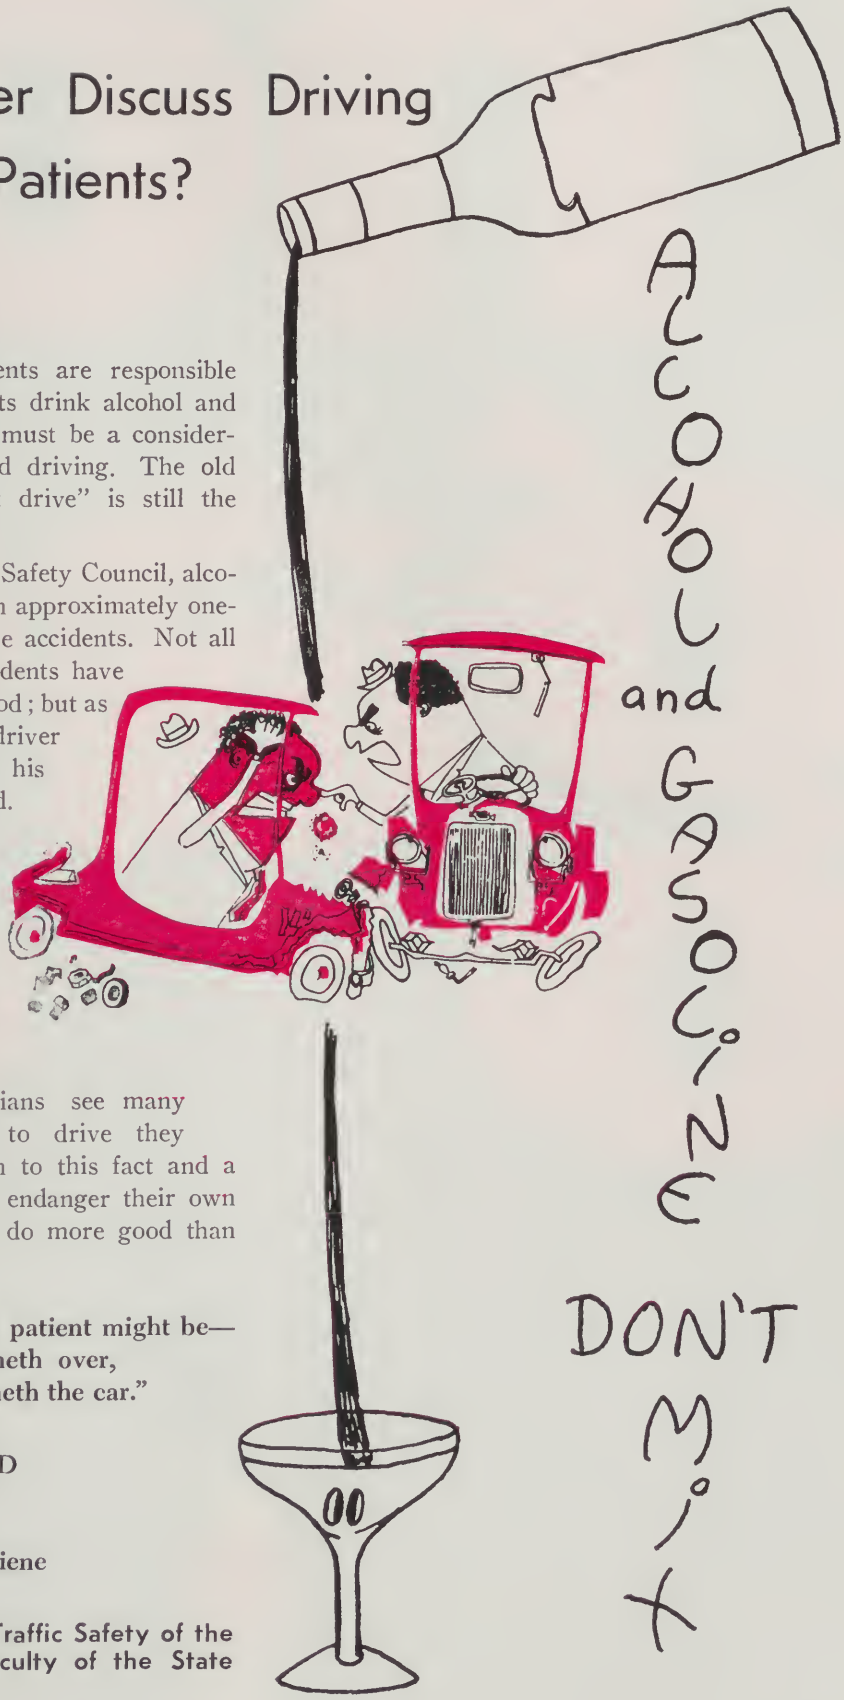
The Judicial Council of the American Medical Association has repeatedly stated that the use of such cards is unethical.

This question was originally considered by the Faculty in 1963 when Central Charge Service of Washington, DC, indicated its wish to offer this service to physicians in the DC area. At that time the Faculty's Council stated:

> **"The Council finds this not in the best interest of the patient-physician relationship and it therefore does not give its approval . . ."**

The Judicial Council of the AMA, following an appeal of the Faculty's decision on the Central Charge Service, ruled:

> **"The Judicial Council of the AMA looks with disfavor on the use of the service of the Central Charge-it Company and similar operations . . . because of the implication of advertising and patient solicitation. Further, the council does not believe that these kind of plans uphold the dignity and honor of the profession."**



Charge Plans should not be confused with "billing services" offered by some groups in Maryland. They should not be confused with "discounting" services offered by other groups.

In essence, these questions should be asked when giving consideration to any type of commercial service offered the physician:

- ☐ Does the use of this service increase, in any way, the cost of medical care to the patient?
- ☐ Does the service interfere with the physician/patient relationship?
- ☐ Are physician's bills rendered in the physician's name and not in the name of the service?
- ☐ Does the physician lose control of the bill and the manner in which it may be collected?
- ☐ Does the display and publication of physicians' names as participants in the program constitute advertising?
- ☐ How does this activity affect the patient's considerations? Does it downgrade the physician's image as being interested only in financial return?
- ☐ How are third-party payments handled? Is the patient entitled to service benefits under his insurance program?

Doctor,
Do You Ever Discuss Driving With Your Patients?

The majority of your patients are responsible people. However, most adults drink alcohol and most adults drive and there must be a considerable overlap of drinking and driving. The old motto, "If you drink—don't drive" is still the best advice.

According to the National Safety Council, alcohol is a leading factor in approximately one-half of the fatal motor vehicle accidents. Not all drivers involved in fatal accidents have high alcohol levels in their blood; but as the percentage increases the driver becomes more cocky and his judgment becomes impaired. In other words, the effect of alcohol on drivers is both physical and psychological. The combination of drugs and alcohol may be particularly dangerous when each re-enforce the effect of the other.

It is obvious that physicians see many patients whose ability to drive they question. A frank discussion to this fact and a statement that they not only endanger their own life, but that of others, may do more good than any proposed legislation.

A parting suggestion to your patient might be—
"If your cup runneth over,
let someone else runneth the car."

DIA-QUEL actually tastes good

DIA-quel contains the only therapeutically active ingredient of paregoric—tincture of opium. This has been combined with homatropine methylbromide and pectin to make a sensible antidiarrheal formula.

By leaving out paregoric's outdated preservative—bitter-tasting camphor—we've produced an antidiarrheal that is good-tasting, as well as effective and prompt-acting in acute, nonspecific diarrheas and their accompanying "cramps." It is DIA-quel, a clear, red liquid with a pleasant cherry flavor.

Each teaspoonful (5 ml.) of DIA-quel Liquid contains:
Tincture of Opium... 0.03 ml.—Equivalent to 0.75 ml. of paregoric.
(Warning: May be habit forming)
To reduce hypermotility and frequency.
Homatropine Methylbromide... 0.15 mg.
A safe dose for mild spasmolysis to curb cramping and griping.
Pectin... 24. mg.
Demulcent, adsorbent. Helps form stools.
Alcohol 10% by volume.

case you're curious, back in the 1700's paregoric was ing used for diarrhea, but since the state of the pharma- utical art was extremely primitive, fungus growth in e medication was a problem. Bitter-tasting camphor as added to prevent such growth and anise oil was lded in an attempt to cover up the camphor taste. IA-quel Liquid is a modern formulation that does not ntain either of these outdated ingredients.

aution: With use of DIA-quel Liquid observe the usual recautions associated with opium derivatives and anti- holinergics.

osage: Usual adult dosage: 1 or 2 tablespoonfuls (15 30 ml.) t.i.d. or q.i.d. Usual children's dosage (Clark's ule): ½ to 2 teaspoonfuls (2.5 to 10 ml.) t.i.d. or q.i.d.

ow Supplied: In 4 fl. oz. (118 ml.) band-sealed bottles.

DIA-quel is a Federally exempt narcotic (Class X) preparation. Where state law permits, no prescription is necessary.

For a complimentary sample of DIA-quel, simply mail your request to us on a signed prescription blank.

KURT GORWITZ, ScD, STATISTICS DIRECTOR

Maryland State department of mental hygiene

Maryland's Privately Operated Psychiatric Hospitals*

Nearly 15% of all psychiatric inpatient admissions in Maryland last year were to the seven privately operated hospitals although these provide 8% of available beds. A slightly larger number were reported to the Psychiatric Case Register as having been admitted to the Veterans Hospital at Perry Point and to other units not administered by the Department. The remaining 70% were to the six state psychiatric hospitals. Patient movement data for the year ending June 30, 1967 are summarized in the following table.

TYPE OF FACILITY	*RES. PATIENT POPULATION 7-1-66*	*ADMISSIONS DURING YEAR***	*DISCHARGES DURING YEAR***	*DEATHS DURING YEAR*	*RES. PATIENT POPULATION 6-30-67*
D.M.H. OPERATED	8,178	11,091	10,439	859	7,652
PRIVATELY OPERATED ...	869	2,284	2,281	33	839
OTHER INPATIENT***	1,635	2,757	2,667	57	1,668
TOTAL	10,682	16,132	15,387	949	10,159

Proportionally, Maryland has always had a substantial segment of its psychiatric patient population treated in privately operated facilities. One of these, the Seton Institute, has been in continuous existence since 1840. It is mentioned by Albert Deutsch in his book "The Mentally Ill In America" as the oldest religiously affiliated psychiatric hospital in the United States. Its history of service is exceeded in this state only by the Spring Grove State Hospital. In Maryland, as throughout the United States, the number of private hospitals has declined in recent years because of personnel shortages, rising costs and other related problems. However, since many of the remaining hospitals have increased their bed capacity, they have maintained their proportion of the total caseload.

Traditionally, the relatively high cost of hospital care in private facilities has produced a patient population with an excess of individuals having the following characteristics: white, female, in the middle years of life (25-54), middle and upper-middle class admitted for the short-term treatment of acute psychoneurotic reactions and personality disorders. Negroes, alcoholics, the senile and chronically ill appeared relatively infrequent. In more recent years the inclusion of psychiatric care in health insurance programs has broadened this population pool. At the same time, tranquilizing drugs, improved standards and the development of new treatment concepts and services have produced major changes in patterns of hospitalization, retention and release of state hospital patients.

Thus, individuals entering public or private psychiatric hospitals are now somewhat more comparable than they have been in past years. The quality and type of services received during hospitalization has also become more similar. Continuation of this trend should produce greater coordination of programs and result in better psychiatric services for all population segments.

* Brook Lane Center, Chestnut Lodge, Gundry Sanitarium, Seton Institute, Sheppard Pratt, Taylor Manor and Washington Sanitarium.

** Does not include placements on or returns from long-term leave.

*** One county operated, one V.A. and three psychiatric units of general hospitals.

DOUGLAS G. CARROLL, MD, EDITOR

rehabilitation notes

Prediction of Performance of Patients With Hip Fracture

"One concern of the writer in the course of reevaluating his own views by tracing current conflicts of doctrine to their sources has been to remedy an increasingly widespread disposition of the younger generation of research workers to relinquish the obligation to examine the credentials of principles invoked in the day's work."

Lancelot Hogben in "Statistical Theory".

* * * * *

In previous publications,[1] a method for collecting data on patients referred to a Department of Physical Medicine and Rehabilitation was outlined. The method is based on the assumption that future performance can be predicted from initial information collected in three areas: ● the diagnosis, ● the activities of daily living (ADL) and ● the degree of orientation (MSCL). In each of these three areas, an ordinal scale has been defined. In Rehabilitation Notes to follow, we will discuss the rehabilitation of patients with specific diagnoses.

No therapeutic procedure is to be followed blindly without careful evaluation of the patients' whole background, attitude and response. Pragmatism, modification, expediency, opportunism, and utility are the sheet anchors of rehabilitation.

We shall, therefore, be particularly concerned with prediction of performance and evaluation of results.

Material and Methods

A group of 183 patients with 185 hip fractures (2 patients fractured each hip at different times) was analyzed. Thirty-five patients had Austin-Moore prostheses inserted and are not considered further in this paper. All types of hip fractures in patients over 15 years of age were included.

Patients were followed in the Department of Physical Medicine and Rehabilitation until they were judged to have reached maximal physical therapy benefit or until they died. Those who reached full independence early were discharged early; those who needed continued physical therapy or medical treatment remained in the hospital until they had reached maximal hospital benefit.

The great majority of patients were seen within a few months of the hip fracture, and weight bearing was not allowed. This report, therefore, is concerned mainly with performance of the patients in early (non-weight bearing) period of convalescence. Those who reached independence in ambulation and stair climbing did so with the help of crutches or a walker. We do not have data on the final performance status of these patients after they had been allowed full weight bearing.

Results

Table 1 is a summary of the findings at initial evaluation plotted against the outcome during the first six months of treatment in the Department of Physical Medicine and Rehabilitation. Results of treatment are judged purely on whether the ADL score increased from a lower ADL score group to 100 (full independence, column 1),

reached a score of 90 to 99 (column 2), improved significantly (defined as reaching any higher ADL score group, column 3), remained unchanged (defined as no change in ADL score group, column 4), or deteriorated (defined as dying or falling into a lower ADL score group, column 5). These are mutually exclusive categories.[1]

It will be noted that 103 (columns 1, 2, and 3) of the 150 patients showed significant improvement in ADL score; 76 (columns 1 and 2) reached a score above 90 and 43 (column 1) reached a score of 100 (full independence in ADL). Twenty-six (column 4) patients showed no significant change in ADL score and 21 (column 5) deteriorated in ADL score and/or died.

Factors on the initial visit associated with improvement in ADL score

The major purpose of this paper is to identify those factors noted on initial evaluation which are associated with improvement in function. One would like to be able to predict which patients will benefit from treatment and which will not.

TABLE 1

RESULTS OF TREATMENT

Summary of findings at initial visit with subsequent results of treatment in 150 patients with hip fractures		Total Cases	1 Reached full Independence: ADL Score 100	2 Reached ADL Score 90-99	3 Reached ADL Score Less Than 90	4 Unchanged ADL Score	5 Deteriorated in ADL Score or Died	Column
Cases:		150	29*	22*	18*	17*	14*

* Numbers are percentages of the numbers in the Total Column.

Although prediction can never be entirely accurate, the method outlined herein should be superior to pure clinical impression. Furthermore, the patients who are expected to do poorly may benefit from special measures taken early.

AGE: It is clear from the study of Table 1, that age is an important factor in improvement in ADL score. This conclusion is supported by three related observations. First, patients who reached full independence (column 1) contained the largest per cent (65%) of the youngest age group—40. Secondly, patients under 59 constitute the largest number, 26, of all those who reached full independence, 43. Thirdly, comparing the different ages of patients in the different final ADL score group (columns 1 to 5), there is a tendency for the percentage of elderly patients to increase in age as their final independence category (as measured by ADL score) decreases. Thus 60% of those who reached full independence (column 1) were under 59. Among those who deteriorated or died (column 5), 95% were over 70.

SEX: Table 1 suggests that men were more likely to improve than women. This is supported by the higher per cent of men than women in column 1, and the fact that 52% of all those who reached full independence were men, although there were fewer men than women in the total series. However, it is noteworthy (column 5) that more men than women deteriorated both proportionally and absolutely. Thus the men were less likely to remain stable in performance (column 4); they tended either to improve or deteriorate, while the women were more likely to remain unchanged (column 4).

DURATION: Surprisingly, the duration of the hip fracture at the time the patient was first seen in the Department of Physical Medicine and Rehabilitation did not seem to be of overriding importance as far as future performance was concerned. The number of patients who had fractures for longer than six months (groups 4 and 5) is too small to be conclusive. If all patients with duration less than one week are compared in columns 1 to 5, it appears that patients with a very short duration (one week or less) are more likely to show improvement (columns 1, 2 and 3) than to remain unchanged or deteriorate (columns 4 and 5).

MEDICAL PROGNOSIS: Patients with a good medical prognosis (normal life span) appear to be slightly more likely to reach full independence than those who have poor life prognosis. Furthermore, three times as many patients with a poor life prognosis deteriorated (column 5) than those with a normal prognosis for life.

MSCL SCORE: An initial MSCL score above 30 was present in 91% of the patients who subsequently improved. The MSCL score was below 30 in 72% of the patients who deteriorated or died. The higher the MSCL scores the greater the likelihood of improvement.

ADL SCORE: There were few patients in ADL score groups 81-95 and 96-100. ADL score group 41-60 contained the largest proportion of patients who ended up fully independent. The greatest number of those reaching full independence came from this group. As final independence decreased (columns 1 to 5), the initial ADL scores tended to be lower.

DIAGNOSTIC GROUP: Diagnostic Group 1 includes patients with no other disease or impairment than a fractured hip. Diagnostic Group 2 includes those with hip fractures who have in addition another disease but no added impairment. Diagnostic Group 3 is made up of patients with hip fractures and additional manifested diseases or impairments. Table 1 reveals little difference in prognosis for performance between Diagnostic Group 1 and 2, but both of these Groups end up with higher performance than Group 3. Table 2 shows diseases and impairments associated with the hip fracture in Diagnostic Groups 2 and 3.[2, 3]

(See page 70 for Table 2)

Discussion

A method has been developed to estimate the rehabilitation needs and potential of patients when first seen in a Department of Physical Medicine and Rehabilitation. The method requires evaluation of the patient from the diagnostic and functional (physical and mental performance) point of view using semi-quantitative ordinal scale grading.

This evaluation method has been applied to 150 patients with hip fractures to compare the actual results of treatment with the original evaluation measurements. It is possible to identify those original measurements associated with later improvement or deterioration.

It is obvious that the patients in this study are generally elderly and many have multiple diseases, have physical impairments other than those

22. Unexplained dizziness		1

resulting from the hip fracture, and a high incidence of mental difficulties. This selection of patients mirrors the hospital population of elderly Welfare patients. Furthermore, patients who were able to master crutch walking easily were often discharged from the hospital without referral to the Department of Physical Medicine and Rehabilitation.

Because of small numbers and ordinal type scales used in evaluation, rigorous statistical methods cannot be applied to the material collected. It is, however, possible to identify certain features found at initial evaluation which are favorable or unfavorable for future improvement in physical function.

A Prognostic Index

Schnur [4] and Peel [5] developed prognostic indices for patients with acute myocardial infarctions. By scoring different historical features and physical findings at admission, they have been able to correlate the initial score with mortality rate during hospitalization. We have attempted to develop such a prognostic index, not for mortality but for physical performance. The question asked at the initial evaluation is whether the patient can benefit from treatment in the Department of Physical Medicine and Rehabilitation. Thus we are interested in treating not just those patients who can reach high levels of independence, but all who can benefit at all from treatment.

Table 3 shows a prognostic index derived by trial and error for the prediction of future performance (as measured by the ADL score).

TABLE 3

Tentative Prognostic Index in patients with hip fracture.

Item	Score
SEX: Female	1
AGE: 60-69	1
AGE: 70-79	2
80+	3
Duration: Greater than 1 month	1
Initial MSCL Score 0 to 10	5
Initial MSCL Score 11 to 20	3
Initial MSCL Score 21 to 30	1
Initial ADL Score 0 to 20	3
Initial ADL Score 21 to 30	2
Initial ADL Score 31 to 40	1
Medical Prognosis: Decreased life expectance	1
Diagnostic Group 3.	2
Worst Score	15

Table 4 shows the application of the prognostic score to the 147 cases of hip fracture in whom the initial data was complete. The largest number of cases have low prognostic indices. All patients with 0 prognostic index reached full independence, and as the prognostic index increased, the patient was less likely to improve in ADL score until with a very high prognostic index there were no cases which improved in performance. Ninety-six percent of the patients with prognostic indices of 4 or less showed some improvement in ADL score. Only 46% of those with indices greater than 4 improved and fewer reached high degrees of independence in ADL.

It must be emphasized that the prognostic index is derived from a small number of highly selected

cases and is meant only as a supplement to clinical impression. It is, however, a step toward identifying factors of importance in regaining physical independence after a hip fracture.

The Natural History of Hip Fracture

The majority of patients in this study had physical and mental limitations not directly attributed to the hip fracture. What are some of the factors which explain poor physical and mental performance in patients with hip fracture?

■ Selection of Cases: It has been pointed out that the Baltimore City Hospitals tends to accumulate patients with multiple chronic diseases and major social problems. The patients who perform well following surgery for hip fracture are discharged home and may never be seen by the Department of Physical Medicine and Rehabilitation.

■ Inactivity: It is our impression from the history and from the examination of feet for calluses, that the majority of patients who suffer hip fractures have been inactive for a prolonged period prior to the fracture. There has already been a general decline in physical and mental activity in many of our patients before they suffer a hip fracture.

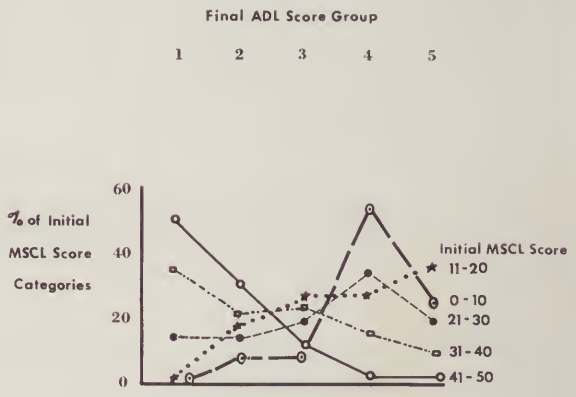
■ Associated Diseases or Impairments: It was pointed out above that patients placed in Diagnostic Group 1 generally had only one manifested physical impairment, *ie,* hip fracture. Some of these manifested evidence of "Chronic Brain Syndrome". Others had subclinical diseases which might not be identified during hospitalization. Table 2 shows some of the diseases associated with Diagnostic Group 2 (unmanifested in terms of performance) and Diagnostic Group 3 (symptomatic).

■ The Hip Fracture: The actual fracture of the hip often proves to the patient that he is no longer capable of walking safely. It then may be very difficult to persuade him that he should even try to walk again.

■ Mentational Status: Thirty-eight per cent of the patients had MSCL scores of 30 or less, indicating moderate to severe mental deficits. These low MSCL scores are the result of a number of factors. The patients seen in this hospital come from the lowest economic and educational group. After retirement, with the decrease in physical activity, there may be an associated emotional withdrawal. A number of patients had symptoms suggestive of intermittent cerebral ischemia as well as frank atherosclerosis. Some had no abnormality on general history and physical examination, but had very low MSCL scores suggestive of "Chronic Brain Syndrome".

Hospitalization itself may have a deleterious effect on patients in borderline mental compensation. The new environment, anesthesia, confinement to bed, various medications, the separation from familiar surroundings and people, may all contribute to disorientation and depression particularly in elderly patients with limited range of mental adaptability.

In brief, fracture of a hip often does not occur by chance. It is a symptom of the physical and mental deterioration which occurs commonly as a result of aging and multiple diseases.



Summary

One hundred fifty cases of hip fracture of all types have been studied in an attempt to identfy what features of the patient's situation seen at initial evaluation are of importance in prognosis for performance of activities of daily living. A prognostic index helpful in predicting final ADL score has been derived. Initial evaluation of physical and mental function are the most important initial findings on which to base prognosis for physical performance.

Addendum

The weight to be given to each initial finding in estimating the Prognostic Index can be demonstrated in Graph 1. This graph is made directly from Table 1. It adds no new data, but possibly the graph allows easier visualization of the relationships. On the ordinate is the percent of patients in each initial MSCL score group who end up finally in each of the five final ADL score groups (abscessa). Thus of the initial MSCL score group 0 to 10, 0% ended in Column 1, 8% in Column 2, 15% in Column 3, 54% in Column 4 and 23% in Column 5. This MSCL score group had none of its original members end up in Column 1. Thus we assign a value of 1 point against this MSCL score group because none of its members reached full independence. If we look at the other columns, we see that there is in addition a tendency for patients in initial MSCL group 0-10 to fall into the poorer final ADL score groups. This tendency re-enforces our impression of poor performance, and we add a second point against this group.

GRAPH 1

If we now compare the trends of the different MSCL groups in Graph 1, we see that they not only tend to arrange themselves in order of descending percentage in Column 1 but do the reciprocal in Columns 4 and 5. Thus there is a very strong, regularly shifting relationship between initial MSCL score and final ADL score group. Therefore we give a maximum value of 5 points against the lowest MSCL score group.

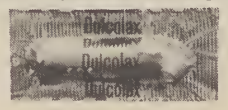
Public Enema No.

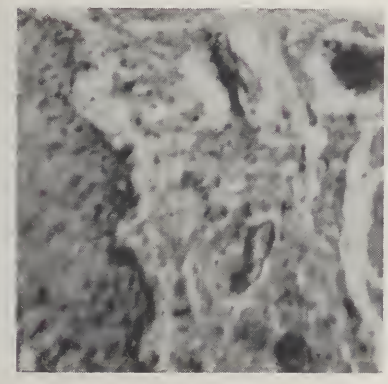
Claim the rewards of sparing your patients the tubes and tribulations of unpleasant enemas.



Compared to enemas, Dulcolax suppositories are a gentler and simpler way to empty the bowel. Gone are the tubing, the "accidents", and the bruised egos. Just one suppository, inserted against the bowel wall, usually brings about an evacuation within 15 minutes to an hour.

In the hospital, order Dulcolax for constipation or bowel cleansing. Your patients will often prefer it embarrassing enemas. And you can be sure nurse will appreciate the saving in time and effort.

Dulcolax tablets taken at night usually result in a bowel movement the following morning. A combi tion of tablets at night and a suppository the next morning generally cleans the bowel thoroughly in preparation for surgery or special procedures. Ke in mind, however, that the drug is contraindicate the acute surgical abdomen.



Dulcolax®...it's predictable

pathology

Innovations in Blood Procurement

Procurement of blood of high quality in amounts sufficient to meet the needs of all patients at all times with a minimum of out-dating is a constant major problem for the average hospital blood bank. Through the years the American Red Cross and more recently the Maryland Blood Exchange, under sponsorship of the American Association of Blood Banks, have provided a major portion of the blood used by the community. Peaks and valleys are frequent, however, since it is difficult to coordinate patient need and procurement by these methods. Also, these operations depend upon motivation of the public to donate. Consequently, major effort by individual blood banks still is necessary to insure a supply that is appropriate to the demand and to combat the persistent problem of out-dating.

Three innovations in blood procurement have been instituted at the Greater Baltimore Medical Center since the opening of the hospital in 1965. These programs, combined with standard hospital blood procurement practices, have produced significant improvement in patient care and in Blood Bank efficiency and economy.

Employee Blood Assurance Program

This program, modeled after the American Red Cross Blood Assurance Programs but with important differences, is offered to all permanent hospital employees. The employee (or a satisfactory donor substitute if the employee is not eligible as a blood donor) agrees to donate blood when called upon but not more than twice a year. In return, the hospital guarantees the full replacement of all blood used by the member employee and most members of his family and household, including in-laws. At the time of entry into the program, the member or his donor substitute is preprocessed with regard to history, hematocrit, serology, atypical antibodies and blood group and type, and in some cases antibody titering. This data, as well as his work hours, date of last donation, hours of availability and pertinent phone numbers are kept on file and the donor is called for a specific blood need according to a patient's blood requirement. Type-specific blood thus can be obtained fresh and to order. Since donors are drawn according to current need, out-dating of blood is decreased. Credits obtained through these donations are transferable to any other hospital in the country through the American Association of Blood Banks and the American Red Cross.

More recently this program has been opened to non-employees who are recruited at the time of a replacement donation for a patient. In three months, 85 non-employee families have been processed into the program; these members, if anything, are more enthusiastic about the program than are the employees.

Obstetrical Blood Assurance Program

The expectant mother, through her obstetrician, is asked to provide one donor prior to termination of her current pregnancy. The program is not mandatory; however, success is achieved by the fact that in return the hospital assures the full replacement of all blood used during that pregnancy.

Predeposit For Elective Surgery

By means of letters to the attending surgeon, patients scheduled for elective surgery on whom blood coverage is requested are asked to provide donors prior to admission to the hospital, equal to the number of units of blood requested by the surgeon. Again, the program is not mandatory but has been successful by working through the attending physician and by being better able to assure blood coverage at the time of surgery. Predeposit by the patient himself is also encouraged; a unit of blood may be drawn about 18 days prior to surgery and held for that patient only.

Through these programs, the blood bank can provide freshly drawn blood of a specific or unusual type more readily and upon request. Dependence upon commercial and other outside blood sources is greatly reduced. Quality control of blood is enhanced since the blood is under "house" control from donor to patient. In each program blood donation is strictly voluntary but because of the inducements offered and the interest stimulated, the result is effective blood procurement.

The large back-up provided by the preprocessed walking donor list is of inestimable value in procuring type-specific blood in emergency situations. Far less effort and time are expended on donor procurement and procurement of bank blood from outside sources. Easing of the burden of blood procurement produces a more satisfactory work environment in the Blood Bank and provides for better relations with the medical staff when their blood needs can be met with regularity. The Obstetrical Blood Assurance Program and the Predeposit Program, although not type-specific drawing programs, provide an important back-up for the routine replacement methods which so often lag, particularly on weekends or holidays.

The patient and the hospital have been the clear beneficiaries of these programs. Because of a lack of need, the paid professional donor is unknown in this hospital. Dependence upon outside blood sources such as commercial blood banks and the Red Cross has decreased markedly. The least expensive blood is blood drawn and processed at the place where it is to be used. Blood procurement costs to the hospital and thus to the patient are reduced and the patient receives better quality care. During the 38-month period from September 1965 to November 1968 this blood bank obtained 154 pints of blood (all drawn for type-specific need) from the Employee Blood Assurance Program and replaced a total of 16 pints to three members of that program. The Obstetrical Blood Assurance Program yielded 520 pints of blood in the same time period, while blood usage by these patients totaled 22 pints. Encouragement of predeposit yielded 384 pints of blood in 22 months from donors provided by patients about to undergo elective surgery; these same patients used 86 pints of blood during their surgery. Therefore, the total blood *credit* or excess from these three programs was 934 pints in three years. During the same period, with the help of these programs the blood bank of this hospital was able to reduce its blood deficit to the Red Cross from 755 pints to about 100 pints.

We believe that these programs, especially the Blood Assurance Program, can be utilized effectively by most other hospitals. With the hospital as the base, such programs could be extended in the community to involve virtually all families not covered by Red Cross or other programs. Administrative detail with a type-specific assurance program is increased considerably and modern data processing support is mandatory for such a comprehensive program. However, with such support there would seem to be no deterrent to the development of a program encompassing virtually all uncovered population in the metropolis, providing a massive walking donor file, preprocessed and listed as to qualifications and availability, for use at any hour for any need by every hospital in the area.

WILLIAM J. PEEPLES, MD, MPH, COMMISSIONER

Maryland State department of health

Highlights

State Health Department Submits Request for 1970 Budget

The Maryland State Department of Health has submitted a budget request of more than $167 million for fiscal year 1970. Almost $100 million of the total request is earmarked for the State's Medical Assistance Program.

It includes 372 positions necessary for the Department to keep abreast of the increasing demands for health-related services. A general breakdown of the 1970 budget request and comparison with 1969 appropriations follows:

	1970 Request	*1969 Appropriations*
Medical Assistance	$ 99,872,712	$ 50,164,821
Local Health Services	30,950,261	26,408,524
Headquarters	7,097,751	4,730,951
Chronic Hospitals	8,861,515	7,353,308
TB Hospitals	3,719,474	3,345,068
Preventive Medical Services	9,039,553	7,079,047
Crippled Children's Services	5,292,203	3,065,850
Environmental	2,832,260	1,763,700
TOTAL Department Request	$167,665,729	$103,911,269

The budget request is almost austere, and in view of the State's serious economic dilemma, it is sure to suffer some cuts during the 1969 legislative session scheduled to begin within the next few weeks. It has become apparent that this year's legislative session will be of more conservative temperament than that witnessed during the last few sessions. Maryland legislators are faced with what is bound to be, to them, the distasteful task of either increasing taxes or severely slashing State spending in an attempt to balance the budget.

Cancer Project Directors Meet

Project directors of cervical cancer screening programs now under way in seven Baltimore area hospitals met November 21 in the State Office Building, 301 W. Preston Street, to report progress and plan future case-finding activities.

The meeting was jointly sponsored by the Maryland State Department of Health and the Cancer Control Program of the National Center for Chronic Disease Control, U. S. Public Health Service, grants from which provide funds to conduct the hospital-based program of cervical cancer detection. Attending the meeting were approximately 40 people.

The Health Department's Division of Cancer Control, under Edward A. Sawada, MD, was instrumental in obtaining the Federal grants for the participating hospitals, which include: Baltimore City, Bon Secours, Provident, Sinai, Union Memorial, University of Maryland, and Spring Grove State Hospitals.

Purpose of the case-finding projects is to establish a uniform program to screen all women hospitalized or treated in hospital outpatient departments for cervical cancer.

U. S. Public Health Service physicians from Arlington, Va., New York City, and Philadelphia reported on their experience in case-finding in these areas. Other speakers included physicians and professional personnel from U. S. Public Health Service, the Maryland State Department of Health, and project hospitals, with additional resource participants from the Baltimore City and County Health Departments, and the Maryland Division of American Cancer Society.

Central Laboratory Location Shifted

The 1969 General Assembly must consider as one of its first acts a change in the law in order to permit the Health Department's proposed six floor laboratory to be built in the new Preston Street Complex. Construction was scheduled to begin on the labs at Guilford Avenue and 20th Street early in the summer of 1969.

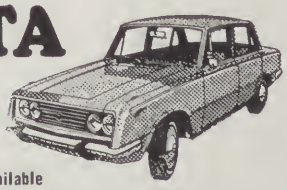
The Preston Complex plans call for further expansion of the present State property that will meet the needs of office space through the year 2000. Included in the plans is a modernistic complex of low buildings that will do for the 300 block of West Preston what the Charles Center is doing for downtown. The plan calls for underground parking, elevated pedestrian walkways, and clusters of buildings allowing the State as much as six million square feet of office space when completed. The plans for the new complex were revealed to State officials on November 15.

During the past year, new branch laboratories in the recently completed Cecil County and the Talbot County Health Centers were occupied. Minor modifications with slight enlargement were completed in the Cheverly Branch and the Annapolis Branch Laboratories. Currently, a complete relocation of the Rockville Branch Laboratory is being planned, and final work drawings are nearly completed for new laboratories at Salisbury and at Cambridge, in new Health Centers. Plans for laboratories in a large Health Center at Cumberland are also in progress.

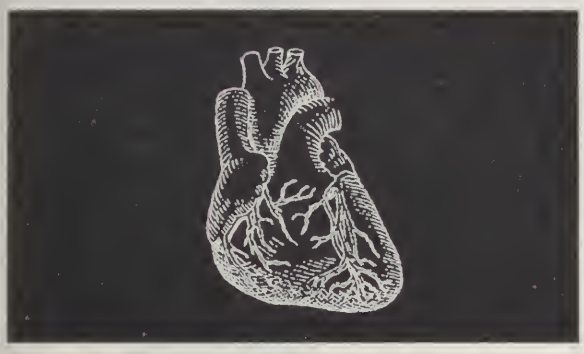
Progress in Water Supply and Wastewater Planning

In 1966, legislation was enacted which requires that each county submit a comprehensive water supply and wastewater plan by January 1, 1970. In October, the Division of Water and Sewerage received from Worcester County the first preliminary draft of such a plan. Several other counties have completed two-thirds or more of the planning effort; however, others are lagging, and the mean progress made throughout the State is approximately 36%. Efforts are being made to accelerate planning activity in those counties that have not yet made substantial progress.

Emergency Health Readiness in Maryland



The State of Maryland ranked among the top nine states in health readiness to meet major emergencies, according to the Division of Health Mobilization's (USPHS) 1968 Annual Report. The report compared all states in eight specific readiness categories: Medical Self-Help Training, Emergency Health Service Training, Hospital Preparedness, Packaged Disaster Hospital Program, Packaged Disaster Hospital Training Program, Hospital Reserve Disaster Inventory Program, City Emergency Health Service Readiness, and State Emergency Health Service Readiness.



The Division of Emergency Health Services is primarily responsible for the eight program areas evaluated in the report.

U. S. Department of HEW Designates D.C. Area as Air Quality Control Region

On October 1, the Secretary of Health, Education, and Welfare formally designated the Washington Metropolitan Area as an air quality control region under terms of the Federal Clean Air Act. The area encompasses Montgomery and Prince George's Counties in Maryland, the District of Columbia, and Fairfax, Arlington, Prince William, and Loudoun Counties in Virginia, and includes the independent cities in those Virginia counties.

Cardiac Amyloidosis

Amyloid is a fibrillar glycoprotein deposited in the tissues of man and animals under a wide variety of clinical and experimental conditions. Pathologically, it is homogeneous, eosinophilic and demonstrates a characteristic green birefringence when stained with congo red and viewed under polarized light.

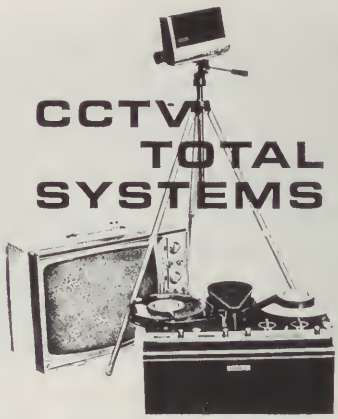
Clinically, amyloid occurs as (1) a primary systemic disease frequently associated with a dysproteinemia, (2) secondary to chronic diseases such as rheumatoid arthritis or tuberculosis, (3) in familial forms, or (4) as localized deposits in single organs.

WERNER F. BARTH, MD
Assistant Professor and Head
Division of Arthritis
University of Maryland Hospital

Cardiac involvement by amyloid may be the predominant clinical manifestation in cases of familial amyloid, may occur in the absence of amyloid elsewhere as in senile cardiac amyloid and is the most common site of involvement and cause of death in the primary systemic form.

Amyloid is deposited extracellularly and interferes with function by encroaching upon and replacing normal tissue. In the heart, amyloid is found in all three layers, the heart valves and in the coronary arteries. Heart weight is often increased but size may appear normal due to loss of elasticity and distensibility.

Congestive heart failure is the most common clinical expression of cardiac amyloid, occurring in approximately half the patients. Failure may be predominantly left-sided, right-sided, or both. Amyloid is a cause of the "Stiff Heart" syndrome and may mimic constrictive pericarditis. In fact, pressure tracings at cardiac catheterization in both familial and primary forms have been similar to those obtained in constrictive pericarditis of other causes. Angina pectoris due to amyloid involvement of the coronary arteries has been described but is infrequent. Involvement of the conduction system may lead to various degrees of heart block and syncope. Orthostatic hypotension is a disabling symptom and reflects autonomic nervous system involvement.



The electrocardiogram is usually abnormal with low voltage, axis deviation and conduction defects all described. The EKG may show Q waves suggesting myocardial infarction but at autopsy this is frequently due to myocardial replacement by amyloid rather than true infarction.

Cardiac amyloid may be an incidental autopsy finding in the elderly, clinically silent, and noncontributary as a cause of death. In a recent series, localized cardiac amyloid was found at autopsy in 10% of people over age 80 and in 50% of those over 90. In those patients with clinical evidence of heart failure, prognosis is

poor once symptoms have appeared. Symptoms are progressive and frequently intractable to the usual modes of therapy, with death occurring in six months to two years following onset of symptoms.

On the basis of our own experience and that of others, caution is advised in the use of digitalis and diuretics in these patients. Digitalis sensitivity on standard doses of the drug, resulting in arrhythmias and even sudden death, has been described by numerous investigators. Maintenance of adequate venous pressure and venous return is important in a "Stiff heart syndrome" such as amyloidosis. Overzealous diuresis may severely reduce cardiac output, leading to renal or cerebral insufficiency.

Amyloidosis should be suspected as a cause of unexplained heart failure in any elderly patient. Index of suspicion should be even higher in those patients with macroglossia, carpal tunnel syndrome or purpura. Hepatic and/or renal failure may also be present. Definitive diagnosis can be obtained by biopsy and congo red stain. Recommended biopsy sites include rectal mucosa, gums, muscle and bone marrow.

Smoking, Sputum, and Lung Cancer

J. Rimington, M.B., Ch.B. *British Medical Journal,* March 23, 1968.

Chronic bronchitis, as evidenced by chronic cough and daily sputum production over a period of years, was the most significant symptom among men diagnosed as having lung cancer following a mass chest X-ray screening. The relationship between chronic sputum production and lung cancer among tobacco smokers was clear. No cancer was found among nonsmokers.

In connection with a mass miniature radiography screening, the relationship between lung cancer, persistent daily sputum production, and tobacco smoking among men 40 years of age or older was investigated. The men were volunteers from the general public and industry.

The subjects were asked whether they smoked or had smoked and, if so, how much they smoked. They were also asked questions about raising phlegm. If sputum had been produced daily for five years, it was considered a symptom of chronic bronchitis. If abnormalities were observed on X-ray film, the individual was referred for further investigation, and six months later a follow-up was carried out. The chest physician who read the original film had no information on the smoking habits and sputum history of the subject.

Lung Cancer Proved

Only volunteers who had lesions confirmed as lung cancer by surgery, biopsy, post-mortem examination, or follow-up were admitted to the study.

Among the 21,579 men in the study, 33 cases of lung cancer were diagnosed. No case was found among nonsmokers. The highest number was among cigarette smokers.

The smoking categories and number of cases of cancer in each were:

Category	*(Subjects)*	*Cases*
Nonsmokers	(2,826)	0
Cigarette smokers	(11,934)	23
Ex-smokers	(4,516)	5
Pipe smokers	(2,267)	5

The rates for lung cancer among the cigarette smokers rose from 1.35 per 1,000 persons for light smokers to 2.47 per 1,000 for heavy smokers. The rate for the group as a whole was 1.93 per 1,000. The rate for ex-smokers was 1.10 per 1,000. The majority of former smokers, including the five who had cancer, had smoked cigarettes.

Risk Declines for Ex-Smokers

These data support findings of other studies that people who had stopped smoking had a lower risk of cancer than current smokers but a greater risk than nonsmokers. Four of the five former smokers who developed cancer had given up smoking only the year before the X-ray examination, which was not the case with the majority of the ex-smokers. It is possible that some of the ex-smokers had developed cancer while still smoking cigarettes.

The rate of cancer among the pipe smokers was

high, 2.21 per 1,000. It may be that previous cigarette smokers were among the current pipe smokers.

In 25 of the 33 lung cancer cases, histologic examinations were made. In 14 persons, the cancer was squamous cell; in five, undifferentiated; and in four, oat cell. Two were adenocarcinomas.

Increased chronic bronchitis mortality with increasing amounts of tobacco smoked has been reported. Several studies indicate that chronic bronchitis and productive cough are both related quantitatively to smoking habits, and the frequency of persistent cough with phlegm has been found to be as high as 42% in heavy cigarette smokers aged 55 to 64 years. In the present series, with its five-year minimum of sputum production, the percentages were lower, as was the average age.

Rates Related to Sputum

The rates of cancer per 1,000 subjects in relation to sputum were as follows: smokers without sputum, 1.30; smokers with sputum, 5.09; ex-smokers without sputum, 0.24; ex-smokers with sputum, 10.13; pipe smokers without sputum, 0.97; pipe smokers with sputum, 13.76.

Lung cancer rates for the subjects with persistent daily sputum are considerably higher than those without sputum in each smoking category. This relationship is also maintained among those with histologically proved cancer, 0.63 for those without sputum and 4.78 for those with sputum. The rates are significant in all categories. (Two cancers among cigarette smokers without sputum were adenocarcinomas, which do not appear to be associated with smoking.)

Since both productive cough and lung cancer are associated with cigarette smoking, it is possible that the high rate of lung cancer among the cigarette smokers with persistent daily sputum for five or more years is due to the association of both conditions with cigarette smoking. In view of this possibility the cigarette smokers have been divided into three consumption categories—light, medium, and heavy—but, irrespective of the amount smoked, the lung cancer rates for those with persistent daily sputum are considerably higher than for those without this symptom.

While a very slow-growing lung cancer could cause chronic cough, it is difficult to believe such a cancer could result in excessive sputum production over a long period of time. None of the volunteers with lung cancer who said they had chronic sputum production had such a respiratory disease as tuberculosis or bronchiectasis to account for the sputum. The reasonable assumption is that the sputum was due to chronic bronchitis.

Smoking Plus Cough

In other studies it has been found that the lung cancer mortality of smokers with a morning cough three years prior to death was three to five times greater than that of those without cough.

It seems clearly indicated that anti-smoking propaganda should be directed at the high-risk bronchitic group, and smokers with a chronic cough or sputum should understand that they are at considerable risk of lung cancer. They should be urged to stop smoking and to seek radiologic supervision.

Many might be sufficiently convinced of the seriousness of their situation to give up smoking. As for the others, early radiologic detection of lung cancer can only serve to improve the chances of a surgical cure, slight though that might be.

Each Cough Calmer™ contains the same active ingredients as a half-teaspoonful of Robitussin-DM®: Glyceryl guaiacolate, 50 mg., Dextromethorphan hydrobromide, 7.5 mg.

Malnutrition in Baltimore's Children

The following report on the problem of malnutrition among Baltimore's children will be of interest to physicians. The analysis and proposals were prepared by Matthew Tayback, ScD, Deputy Commissioner of Health for Baltimore City, with the assistance of members of the Department's nutrition and child health services staff as presented in the Commissioner's *Weekly Letter to the Mayor* dated October 10.

Evidence of Malnutrition

There is unequivocal evidence that malnutrition exists among significant numbers of our children.

1. Among infants seen in well-baby clinics, that is, infants from low-income families and who are 6 months to 2 years of age 75% have hemoglobin values below 11 gms per cent. Among children of similar age and who are from middle-income and upper-income families, less than 10% would have hemoglobin values below 11 gms per cent. Low hemoglobin values indicate iron deficiency anemia. This condition occurs at a rate six-fold higher in low-income infants than among children of more favored economic circumstances.

2. Among preschool age children, 2-5 years of age, who are seen in pediatric centers caring for children from low-income circumstances, the rate of retarded physical development is in the range of 12-15%, four-fold greater than that found in the general population of children. The retarded physical development is believed due to poor nutrition of low-income children, existence of which is confirmed by nutritional surveys undertaken by nutritionists in our Child Hygiene Services section.

3. Among women, who are from poor economic conditions, and who bear children, the rate of birth of premature babies is 16%, which is twice the rate found in mothers from more favored circumstances. It is now believed that this difference is due, principally, to the accumulated effects of poor nutrition among young women who come from low-income families.

Proposals for Correction of Malnutrition

The problem of malnutrition among infants affects not less than 5,000 infants from families in poor economic circumstances. A major impact upon the problem can be made by providing such infants a milk formula fortified with iron and with vitamins. The milk formula should be given for the first six months of the life of a newborn child. A longer period is desirable, but significant changes can be achieved by the six-month program.

Among the 5,000 infants who require fortified milk formula support, 3,000 are located in the Model Cities Area. To support an infant with free milk formula for six months will cost $50 per infant or for 3,000 infants the cost would be $150,000. It is my expectation that this urgent matter will be considered by the Coordinating Council of the Model Cities Agency and I sincerely hope that they may recommend inclusion of this service in the Model Cities program for fiscal 1969. Two thousand infants requiring free milk formula distribution are located outside of the Model Cities Area. A sum of $100,000 needs to be allocated to provide the appropriate prepared milk formula. At the present time, I know

of no other source of funds to achieve this distribution than the general fund of the City.

The problem of malnutrition among children of preschool age is difficult to attack. By and large it derives out of limited economic resources of families on public assistance and in income levels below the poverty level. However, there is a good resource available to assist poor families in obtaining more adequate food. This resource is the Food Stamp program, federally funded, supervised by the U.S. Department of Agriculture, and locally managed by the Baltimore City Department of Social Services. This program is not functioning well in this City.

At a conference which I convened on this program at which representatives of the U.S. Department of Agriculture, the City Department of Social Services, Legal Aid East, and the City Health Department were present, the following observations and recommendations were made:

Participation in this program has not been satisfactory by low-income families, either those on public assistance or non-public assistance. While 90% of all public assistance clients are eligible, only 24% are using the food stamps to purchase their family food supplies. As of September, 1968, there were 760 non-public assistance families using the stamps. It is estimated that the number of such families in need would equal not less than 5,000.

Because of the exceptionally limited participation in the food stamp program, and the demonstrated need, simple changes in procedure need to be made. These are:

1. "Authority to Purchase" cards, now issued monthly, should be issued once each six months.
2. Minimum cash contribution by the family in order to benefit from food stamps should be reduced.
3. Eligible families should be permitted to purchase food stamps on a weekly or biweekly basis.
4. Distribution points for food stamp acquisition should be more accessible both geographically and time-wise.
5. Income eligibility levels for non-public assistance cases should be raised.

We believe that a large number of elementary school children are not receiving adequate lunch regularly. In most communities, the school lunch program is the means by which one is assured that each child will receive an adequate meal at lunch. In Baltimore, we have a school lunch program and other related feeding programs which are not reaching all of the children that are in need. This is due to the fact that (1) cost of lunch, $ .35 per day, is beyond the means of children from low-income families, the number of such children in elementary schools being approximately 30,000, and (2) no school lunch program is available in many inner city schools.

Although it is true that free meals are available, the number of such meals daily is less than 3,000 while the need is close to 30,000. For example, in the City of Washington, with an elementary school population less than Baltimore's, the number of free lunches is 10,000 daily.

In our early study of the matter of feeding school age children we have identified the following federally funded programs which are available.

1. National School Lunch Act
2. Special Milk Program—U.S. Department of Agriculture
3. Breakfast—U.S. Department of Agriculture
4. Child Nutrition Act of 1966
5. Elementary-Secondary Education Act—Title I
6. Surplus Commodities for Group Care of Children

To the best of my knowledge no single agency has assumed responsibility to secure for Baltimore the fullest benefits from these programs. There is a necessity, therefore, for the designation of an agency to work with the appropriate federal and state offices so that Baltimore may better receive an appropriate share of funds allocated for the nutrition of children. For example, in the City of Washington, each child receives daily a half pint of milk without charge (and largely federally funded). No such program of free distribution exists in Baltimore. This may be possible by better utilization of the provision of the Child Nutrition Act of 1966.

The City Health Department is prepared to undertake further work towards strengthening the program for nutrition of low-income Baltimore residents, and to encourage the implementation of the recommendations cited above. In view of the fact that negotiations with federal and state agencies may be necessary, the designation of an appropriate agency to accomplish this should be made by your office.

A Guide: To Help You Find Your Way Around

Periodically, it seems appropriate to inform our readers about the latest reference aids in various subject fields, or biographical and organizational directories. Following are some of the latest biographical listings received by this library.

Biographical Reference Titles

General

International Medical Directory.
Published by World Medical Association, United States Committee, Inc. A limited list by country.
n.d. [1968] **R 10.5 W6**

World Who's Who in Science Chicago, Marquis Who's Who.
A biographical Dictionary of notable scientists from antiquity to the present.
1968 **Q 141 W6**

Canadian Medical Directory, 14th. Toronto, Seccombe House.
Physicians listed alphabetically and geographically. Includes a variety of general topics, including medical associations, schools and journals, hospitals, care plans. . . .
1968 **R 713.01 C3**

The Medical Directory. London, J & A Churchill, Ltd.
Members of the profession in Great Britain listed alphabetically in 2 volumes. The second volume also lists medical schools, colleges and hospitals.
1968 **R 713.29 M4**

American Public Health Association Directory.
Lists members and fellows—alphabetically and geographically. Also names the Governing Council, Affiliated Associations and Regional Branches, Agency Members and Sustaining Members.
1967 **RA 421 A5 1967**

American Men of Science. N.Y., R.R. Bowker Co.
6 volumes containing biographies of scientists in Physical and Biological sciences. 7th and 8th volumes cover the Social and Behavioral Sciences. Entries selected on the basis of 1) Achievement, 2) Quality of research activity, 3) Position of responsibility.
1968 **Q141 A5**

State and Local

Other local rosters are available as published in the respective journals. This list includes only those received recently.

The Johns Hopkins Directory.
Faculty and administrative personnel. Also partial listing of Homewood Campus Officers, and complete department directory for medical institutions, services and clinics.
1968-1969 **R 712.A2 J6**

Louisiana State Board of Medical Examiners.
Physicians, surgeons, podiatrists, midwives and physical therapists who were legally qualified by the state for 1968.
1968 **R 712.A2 L7**

Medical and Chirurgical Faculty of the State of Maryland.
Membership directory by county, with index. Also lists affiliate members; gives specialty, hospital affiliations, and society memberships. Hospitals are listed by county.
1968-1969 **RM A2 M4**

Medical Association of the State of Alabama.
Roster of the Association. List by counties, gives colleges attended and address. Alphabetical list gives telephone number.
1968 **R 15 .A5 M4**

The Suffolk County Medical Society and The Suffolk Academy of Medicine Bulletin.
Tenth annual directory. Hauppauge, N. Y. Members listed alphabetically, geographically and by specialty. Also lists hospitals and community agencies in the county.
1968

University of Maryland Student-Faculty Centre telephone directory.
Information includes address and specialty. Student section also adds year of professional training. Baltimore Campus only.
1968-1969

Specialties

American Association of *Hospital Consultants.*
Directory 1968-69. Information concerning each. Consists of address, present connection, type of service, associates, biography, professional societies.

SKIN PROBLEMS

Caused by itching due to:

Dry Eczema	Acne
Chafing	Ivy Poisoning
Minor Burns	Cold Sores
Athlete's Foot	Heat Rash
Dry Skin	Diaper Rash
Wind Burn	Chapping
Insect Stings	Hemorrhoids

For Safe, Sure, Speedy Relief —
— Get RESINOL GREASELESS!

Medical Scientists have conquered 6 dread diseases in the past decade, but they are largely in the dark, they admit, in finding relief for one age-old ailment—itching

New remedies containing antibiotics have been tested, but have often caused side effects which are worse than itching skin. After many years of research and testing, Resinol Greaseless Cream was developed. . . . A doctor's formula containing safe yet powerful ingredients, Resinol Greaseless contains an amazing, proven "anti-itch" medication called Resorcin, which quickly and effectively relieves most any kind of itching. Try Resinol Greaseless . . . You'll be delighted to find that it really works! At all drug stores. Buy a tube today.

Baltimore, Md. 21201

4 Million Diabetics Here—

Some 1.6 million persons in the United States—a majority of them women—have diabetes and do not know it, the Health Insurance Institute said recently.

Add this to the 2.4 million known diabetics in the U. S. for a total of 4 million—again, the majority of them women—with a disease for which there is no known cure, but which can to some extent be controlled.

It also appears that on the average, women have more severe cases of diabetes than men.

She's Old, Heavy

An analysis of U. S. Public Health Service studies of the "sugar disease" indicates that the type of person most likely to be diabetic is an elderly woman with a weight problem.

These three points stand out:

- Nearly six out of ten known diabetics in the United States are women.
- The prevalence of diabetes increases with age, with a peak in the 65-to-74 age group. Researchers have found that in most cases diabetes is not diagnosed until a person is 45 years or older, perhaps because the disease does not strike until then.
- There is a definite relationship between diabetes and obesity. A recent screening of Federal employees indicated that diabetes occurs seven times more frequently among overweight people compared to those of normal weight.

Stress Weight Control

Most doctors agree that avoidance of obesity is the most important, frequently the only measure, that will help reduce the incidence and severity of diabetes in older people.

The National Health Survey found that women, on the average, were disabled by diabetes for substantially longer periods than men.

1.6 Million Don't Know It

Women had an average of 58 days of restricted activity annually, contrasted with 48 days for men. Women averaged 27 days a year in bed because of diabetes while male diabetics averaged 18 days. This higher level of female disability occurred at all ages except 75 years and over.

The most frequently reported symptoms of diabetes are extreme fatigue, leg pain and eye trouble.

Other symptoms include sudden weakness, frequent urination, thirst, loss of weight, and abnormal appetite, national figures on diabetics show.

In each of these instances, women consistently report more of these symptoms than men. They also report a larger variety of symptoms as they grow older.

Among the most serious characteristics of diabetes is that it often is linked to other chronic conditions.

According to the National Health Survey, four out of five diabetics in the United States have at least one chronic illness in addition to diabetes, while 58% have three or more illnesses.

Can Go Blind

The conditions reported most often were heart problems, hypertension, and impaired vision and blindness.

In a study of 17 chronic illnesses most often found in diabetics, women were usually more affected by these conditions often by a ratio of at least two to one.

Amputated fingers or toes, the absence of major extremities, and tuberculosis were characteristics most often found among male diabetics.

Probably the most sobering fact about the disease is that most medical men agree that despite advances in care, the primary goal of prevention or cure of diabetes is far from being met.

We lease car,

not cars (plural). Car (singular). When a professional man like you wants just one car.

We do one-car-at-a-time leasing with plans particularly appropriate for the professional man. Plans designed to give you the same advantages as enjoyed by big companies that lease.

These advantages include: the new '69 you want as you want it, no capital tied down in a depreciating asset, no separate maintenance or insurance bills, convenient service without extra charge at thousands of "Happy Motoring"® stations throughout the United States, exact transportation costs records on a single monthly bill for tax accounting, no trade-in problems or losses.

Many physicians and surgeons are now leasing. With good reason. Ask your nurse or secretary to drop us a note, or call us, for a detailed booklet explaining the Humble Leasing Plan.

Man in space, now fait accompli, re-emphasizes the importance of Uro-Phosphate therapy. Research into the effect of space travel on the astronaut reveals that weightlessness causes loss of bone calcium. As the bones are required to bear less and less of the weight of the body they lose calcium, increasing the calcium content of the urine. When physical activity is reduced, the acidity of the urine should be adjusted to keep increased calcium in solution . . . . a prophylaxis to prevent kidney or bladder calculi.

Uro-Phosphate®

NOW A SUGAR-COATED TABLET

Each tablet contains: METHENAMINE, *300 mg.;* SODIUM ACID PHOSPHATE, *500 mg.*

Uro-Phosphate gives comfort and protection when inactivity causes discomfort in the urinary function. It keeps calcium in solution, preventing calculi; it maintains clear, acid, sterile urine; it encourages complete voiding and lessens frequency when residual urine is present.

Uro-Phosphate contains sodium acid phosphate, a natural urinary acidifier. This component is fortified with methenamine which is inert until it reaches the acid urinary bladder. In this environment it releases a mild antiseptic keeping the urine sterile.

Uro-Phosphate is safe for continuous use. There are no contra-indications other than acidosis. It can be given in sufficient amount to keep the urine clear, acid and sterile. A heavy sugar coating protects its potency.

Dosage:

For protection of the inactive patient 1 or 2 tablets every 4 to 6 hours is usually sufficient to keep the urine clear, acid and sterile.

2 tablets on retiring will keep residual urine acid and sterile, contributing to comfort and rest.

A clinical supply will be sent to physicians and hospitals on request.

Novahistine®
Singlet decongestant-analgesic

(Each tablet contains: phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; acetaminophen, 500 mg.)

DOW

Geigy

Regroton®

chlorthalidone 50 mg.
reserpine 0.25 mg.

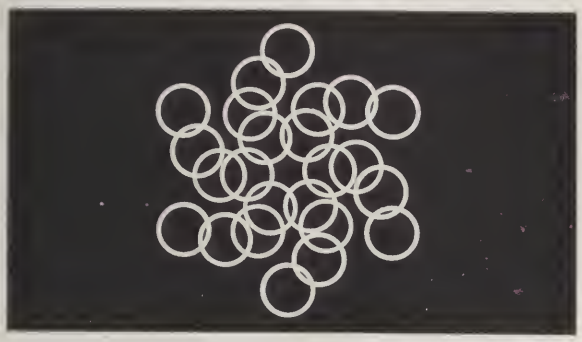
One Regroton tablet a day usually helps you and your patient bring high blood pressure down and keep it down.

Regroton produces a smooth, long-acting effect that usually reduces both systolic and diastolic pressures. At the same time it often acts to allay anxiety and nervous tension associated with hypertension.

Although Regroton is generally well tolerated, adverse reactions may occur. This drug is contraindicated in mental depression, demonstrated hypersensitivity, and most cases of severe renal or hepatic diseases. For a complete list of side effects, please see the Prescribing Information summarized on the following page.

Regroton®

chlorthalidone 50 mg.
reserpine 0.25 mg.



One Regroton tablet a day usually helps you and your patient bring high blood pressure down and keep it down.

Indications: Hypertension. **Contraindications:** History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases. **Warning:** With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs. *Use in pregnancy:* Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. Increased respiratory secretions, nasal congestion, cyanosis and anorexia may occur in infants born to reserpine-treated mothers. **Precautions:** Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue therapy with this agent two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria. Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Severe salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients. **Adverse Reactions:** The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible. **Average Dosage:** One tablet daily with breakfast. **Availability:** Pink, single-scored tablets in bottles of 100 and 1000.

RE-6225

From the Subcommittee on Alcoholism of the Medical and Chirurgical Faculty of the State of Maryland

A Physician Considers His Responsibility for Treating Alcoholics

Alcoholism has officially been considered an illness by the AMA for more than ten years, but only recently is it being accepted to any appreciable degree by individual physicians, and by society, as an illness.

RICHARD H. ANDERSON, MD *

I firmly believe alcoholism is an illness, an illness for which the alcoholic cannot be held responsible or be condemned. It is a chronic disease, with characteristic relapses even after treatment has commenced. Too often, we shame the alcoholic or show our disgust for him because of his breaking a promise to remain sober, but he is *addicted* to alcohol!

Professionals from many fields have been neglecting the alcoholic: nurses, social workers, ministers, vocational rehabilitation counselors, probation officers, judges, police and, of course, physicians. All of these people come in contact with the alcoholic when he is down, when he is most vulnerable to treatment and rehabilitation. All of them, and society in general, which is probably partially responsible for the illness, have an obligation to assist the five million alcoholics in this country, but few are meeting this responsibility.

Physicians have the biggest responsibility. We are often in a position to diagnose the illness before anyone else, simply by taking an adequate history and examining the patient. We see the patient when he has the shakes and can't sleep, when he has alcoholic gastritis, when he wrecks his car, when he is hit over the head with a beer bottle, and when the police drop him drunk at our hospitals.

We have the responsibility to diagnose the illness, to treat the acute stages, to confront the alcoholic with the diagnosis, and to refer him to the proper treatment program. We have not met this responsibility. Because conventional psychotherapy proved ineffective, and because alcoholics often seem unmotivated, most psychiatrists abandoned them; because alcoholics do not follow instructions and are not dependable, and because their symptoms are frustrating, most general physicians abandoned them. Because of their own ambivalent feelings about drinking and inability to understand that will power alone won't work with alcoholics, their families and society in general abandoned them.

* Dr. Anderson is a member of the Faculty's Subcommittee on Alcoholism. The above paper is revised from an address he delivered before the Harford County Medical Society, October 16, 1968.

A recovered alcoholic is writing a series of articles on alcoholism for a Baltimore County weekly newspaper. One of his articles concerns the medical profession.

". . . Many law enforcement officers, judges, lawyers, ministers, social and welfare workers have repeated opportunities to help as they encounter alcoholics during crisis situations and more times than not they fail. And what about doctors and nurses?

"The medical profession is in an excellent position to wave the red flag in the face of the developing alcoholic. But too frequently this does not occur. I have heard many recovering alcoholics tell of their first encounter with the family physician over the amount of booze consumed. Usually the advice they received was, 'Cut it down to one or two a night'; or, 'Just drink beer'; or 'Stop'. The 'Stop' may also be accompanied by a prescription for a tranquilizer. And the alcoholic addict bounds off with a ticket for another hang-up in addition to his alcoholism. . . .

"I suppose, to be perfectly fair, that we can't lay all the blame at the feet of the doctors and nurses. After all, until just the last few years, medical schools have offered little meaningful education regarding this illness. A doctor friend of mine has told me that if a doctor is over 35, he has probably received no more than one or two hours of education on alcoholism, the illness that ranks fourth on the list of public health problems. I once heard another doctor say that his one hour lecture on alcoholism consisted of detailed instructions on how to get a drunk out of the waiting room without disturbing the rest of the patients!

"Is this all that we can expect from our medical schools and the products that they turn out? Fortunately some few doctors and nurses have educated themselves about alcoholism and they work very effectively with alcoholic patients. But shouldn't all of the graduates from our medical and nursing schools be equipped to identify and treat the alcoholic?

"This will not happen overnight. And my frustration will continue at least for a while, especially when I think of the millions of alcoholics who have prematurely died over the last 20 years or so. Their death certificates do not show alcoholism; more likely they show cirrhosis, heart disease, stroke, T.B., or auto accident, but seldom alcoholism.

"Is it any wonder that the anger boils up inside when I ask someone to help an alcoholic and I get a shrug of a shoulder or a reply, 'Why?' I hear 10,000,000 reasons whisper back, 'Why not?' "

The Comprehensive Intoxication and Alcoholism Control Act was recently passed by the State Legislature. For the first time, that I'm aware of, a group of lay people told us, the medical profession, how to treat a particular disease. They don't tell us how to treat diabetes, heart disease, or cancer! They told us that alcoholism is a disease, and that we must have detoxification units in our hospitals for the detoxification or drying out of drunks. An insult! *But* we have not met our responsibilities as physicians.

This law does not allow the alcoholic to continue to be treated as a criminal, and it does not allow physicians and hospitals in Maryland to continue turning their backs on alcoholics. Now as winter is coming, our hospitals and emergency rooms are going to be overflowing with drunks. It is unfortunate that hospital administrators were not included in the planning of this bill, and it is unfortunate that the appropriations bill which accompanied it was not passed, but we have to do the best we can. I don't know how hospitals are going to cope with the expected increase in volume, but they must make more effort: It is the law.

Treating the alcoholic for alcohol withdrawal is not difficult 95% of the time. It does not usually require a private room, a private nurse, a locked door, restraints, or prolonged hospitalization. It does often require a thorough work-up for medical complications of alcoholism, adequate sedation with one of a number of tranquilizers, vitamins and an adequate diet, and then referral to the local alcoholism clinic and/or AA group, and perhaps referral to a state hospital for longer hospitalization and rehabilitation. Delirium tremens, which is relatively uncommon and which is a true medical emergency with a 5-30% mortality rate even with treatment, often does require restraints, private nurses and extensive medical care. But D.T.'s can be prevented by treating the alcoholic in the early withdrawal phase instead of letting him dry out at home.

If physicians will accept alcoholism as an illness and not a moral problem, and will accept intoxication as an exacerbation of the illness, there cannot be resistance to the general hospital treatment of alcoholics. If physicians realize that alcoholism is the fourth major health problem in the country, that there are five million alcohol

addicts and 20 million problem drinkers in the country, how can hospital treatment be denied? If physicians will realize that they can initiate a recovery that does indeed occur, and if physicians realize that alcoholics can be useful citizens, how can they deny them treatment?

Let's ask ourselves where the intoxicated alcoholic should be taken for treatment? Jail? He is not a criminal. The State hospitals? They are understaffed and staffed mainly by psychiatrists who should not be treating the medical problem of the acute withdrawal syndrome. His home? It is often a single room, a flophouse, or the street, where he will only drink again, or die with D.T.'s. Or the hospital? Is there really any choice among these alternatives?

Let us begin treating the alcoholic as a sick person with all the dignity, compassion, patience and understanding physicians are expected to have.

No injection after all!

This penicillin produces high, fast levels—orally.

Pen•Vee® K is usually so rapidly and completely absorbed that therapeutic penicillin levels are attained within 15 to 30 minutes. Thus it can often obviate the need for penicillin injections. The higher serum levels produced generally last longer than with those of oral penicillin G.

Indications: Infections susceptible to oral penicillin G: prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.
Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.
Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.
Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.
Adverse Reactions: (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").
Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

(potassium phenoxymethyl penicillin) Wyeth

Medical Personnel Shortages Polled

America's doctors say their communities are having moderate-to-severe nurses shortages.

The opinions were compiled in a monthly opinion poll conducted nationally among physicians by Marion Laboratories, Inc.

The Playback poll was answered by 1,156 doctors.

Fifty-nine percent of these physicians agree there is a nurses shortage. This is in close agreement with a poll of the general public announced in May by George Gallup. Cardiologists answering the Playback Poll apparently feel the nurses shortage the worst, "other specialists" the least.

Geographically, the nurses are in too-low supply everywhere, but especially in Arizona, Georgia, Illinois, Louisiana, Mississippi, New Jersey, Oklahoma, Texas, Utah, and West Virginia.

The doctors feel there are doctor shortages, too, in some communities, especially in Arkansas, Iowa, Maine, Montana, North Carolina, and Nevada.

Expansion at the University of Maryland

The next campus building to be completed will be the Shock Trauma Center, which will probably be occupied late this year. The center was planned around a 12-bed patient area on the top floor, with labs quickly accessible on the third floor directly below. The second floor is reserved for operating rooms and a cardiac catheterization lab and the first floor for offices.

A high pressure chamber on the ground floor will be used to treat shock by literally drenching needy tissues with oxygen.

Under the direction of R. Adams Cowley, MD, a full-time staff of doctors, nurses, and technicians will gradually be assembled to man the center 24 hours a day. With the cooperation of the City and State, a helistop is being planned for the future, to speed arrival of patients in shock, particularly those severely injured in highway accidents.

State Medical Examiner's Building

On the corner of Pratt and Penn streets, the state medical examiner's building is nearing completion and will be occupied in 1969.

A basement and three floors will provide 30,000 square feet, of which 7,000 square feet on the top floor will be devoted to research and teaching under the direction of Russell Fisher, MD, who besides being chief medical examiner is professor and head of the medical school's division of forensic pathology.

School of Dentistry

During the fall of 1969 the six-story dental school building should be completed. It will permit expansion of the entering class from 100 to 128 students, and will provide space for training dental hygienists and dental assistants.

The curriculum changes that were planned in conjunction with the new building will put the school in the forefront of dental education, according to Dean John J. Salley.

School of Nursing

Construction of a new building for the School of Nursing at the corner of Penn and West Lombard streets began in July.

Dean Marion I. Murphy reports that the new six-floor building will provide 59,710 square feet of space to accommodate growing classes. Completion is expected by the summer of 1969.

North Hospital

Bids for the new North Hospital Building, which will almost double present hospital space, were opened October 24. When this building is completed in 1970, along with the contemplated 13-story addition to Howard Hall and continued modernization of the present hospital, this campus will be far better equipped to fulfill its essential new role in health education and service to the citizens of Maryland.

Baltimore City Medical Society

Minutes

Eight of the members of the Board of Directors of the Baltimore City Medical Society met on November 12, 1968. The meeting was called to order by D. Frank Kaltreider, MD. The minutes of the October 8th meeting were read and approved. The first item on the agenda was a correspondence from Gustav G. Voigt, MD, informing Dr. Kaltreider that the regional advisory group of the Regional Medical Program approved the cardiac ambulance proposal. Dr. Voigt informed the Board that the proposal now goes to Washington and if approved there, funds may be available to launch the program in July 1969. Dr. Voigt expressed his gratitude to the Executive Council of the Baltimore City Medical Society for their support and agreed that regular meetings between the Project Director and the Baltimore City Medical Society should be arranged and felt this step was important in establishing communication and rapport between the interested groups.

The next item on the agenda were committee reports submitted to Dr. Kaltreider from the various committees of the Baltimore City Medical Society. These reports were read and were to be distributed at the Society's Annual Meeting in December. They are also on file in the office of the Society for those who are interested. Of special interest was the committee report submitted by Philip F. Wagley, MD, Chairman of the Policy and Planning Committee. This important committee submitted a list of five recommendations to the Board of Directors. The First recommendation was that the Society continue to participate in discussions of the Health Sciences Consortium so that the Society can keep abreast of development in health education and possibly formulate contributing roles. Secondly, letters were sent to 17 State Medical Societies in connection with considering the role of an executive director. Fifteen answers were received. After much discussion by the Policy and Planning Committee, it was recommended that no executive director or secretary be appointed at this time. It was the consensus of this committee that no lay person, and no one individual physician can substitute for increasing involvement in participation of a part of the membership of this Society. Thirdly, and along the same line of thought, the Committee recommended that candidates for membership in this Society be required, before admission, to attend at least two orientation meetings where they would be informed as to the role of this Society in the community life. Also, it is recommended that the Society assess the particular interest of the candidate so that their services may be more fully utilized. The Committee thinks the admission of candidates at this time is so casual and rather routine so that the new member is not stimulated to play a truly participating and contributing role in the functions of the Society. Fourthly, it has been the consensus of the Committee that the socio-economic problems remain important ones for the Society. Along that line, at the last meeting of the Committee, the suggestion was made that funds be set aside for use in the following general manner; to defray a significant amount of the cost of the pre-medical and medical education of some young student in the inner city. Consideration might be given, for example, to a trainee in paramedical studies in the Dunbar High School. Many details and lines of guidance will have to be formulated explicitly for this. However, the present Committee suggests that this is a topic of study for the next Policy and Planning

Committee. Fifthly, and obviously, the current Policy and Planning Committee recommends most strongly that the work of the Committee be carried on through the appointment by the next President of a similar group.

A letter was read from the President of the Woman's Auxiliary of the Baltimore City Medical Society, Mrs. Karl F. Mech, informing the Board of Directors that the Woman's Auxiliary is in need of financial and clerical help. After some discussion by the Board of Directors, it was decided that Mrs. Mech should be invited to the next meeting of the Board of Directors and more explicitly outline her problems and needs.

Under new business, the Society was solicited by "The Orthopedic Research Foundation" for funds. It was decided by the Board that, although the Board encourages the function of this foundation, and is sympathetic towards their cause, funds were not available for contribution from the Society.

Marvin Schuster, MD, presented an outline protocol to the Board of Directors pertaining to the training of ileostomy and colostomy patients. This protocol was to be submitted to the Regional Medical Program Committee for their support. Dr. Schuster requested that the Board of Directors lend support to such a program. After some discussion, the program was approved by the Board of Directors and they agreed to support its institution.

The next item under new business was a discussion and the appointment of a committee to negotiate and arbitrate for purposes of unification of the two existing City Medical Societies.

The meeting was adjourned at 5:30 PM.

ARTHUR E. COCCO, MD
Journal Representative

Montgomery County Medical Society

Merton L. White, MD, a Silver Spring physician for the past 20 years, has been elected the 65th president of the Montgomery County Medical Society.

A native of Buffalo, New York, Dr. White graduated from Georgetown Medical School in Washington, D. C. He served in the United States Navy during World War II and still holds a position in the Navy Reserves.

Dr. White brings much experience to the office of president, having served the Society as treasurer and vice president, as chairman of the Professional Relations Committee and as a member of the Legislative, Constitution and Bylaws Committee.

At the Society's Annual Dinner Dance held at the Woodmont Country Club, the responsibility of the presidency and the gavel were transferred to Dr. White by Marvin I. Mones, MD, retiring president. Dr. White, in turn, presented Dr. Mones with the Past President's Plaque.

Howard County Medical Society

At the last bi-annual meeting of the Howard County Medical Society, the following officers were elected for two-year terms beginning this month:

President is Peter Van B. Thorpe, MD; George Burgtorf, MD, is vice president; Art Panayis, MD, secretary; Theodore Shrop, MD, treasurer; Thomas Herbert, MD, was chosen as delegate to the Medical and Chirurgical Faculty, and Justinas Kudirki, MD, was elected alternate delegate.

Information for Authors

MANUSCRIPTS: Manuscripts will be accepted for consideration for publication with the understanding that they are original, have never before been published, and are contributed solely to the Maryland State Medical Journal.

All manuscripts are acknowledged upon receipt and are followed up by notification of either acceptance or rejection. Rejected manuscripts are returned by regular mail. Accepted manuscripts become the property of the Journal and are not returned. The Journal is not responsible for loss of manuscripts through circumstances that are beyond its control.

Manuscripts should be addressed to: Editor, Maryland State Medical Journal, 1211 Cathedral St., Baltimore, Md. 21201.

SPECIFICATIONS: Manuscripts must be original typed copy, doublespaced throughout (Including text, case reports, legends, tables and references) with margins of at least 1½ inches. Pages should be numbered consecutively.

The manuscript should include the title (brief and concise), the full name of the author (or authors) with degrees, academic and professional titles, affiliations, and any institutional or other credits. Please include a complete address where the author may receive proofs of his article for his approval and corrections.

All manuscripts should be accompanied by a carbon or xerox copy and the author should retain another copy for his records.

TABLES: Each table should be typed on a separate sheet of paper, be numbered, have a brief descriptive title, and its position in the text should be indicated.

Be sure that statistics are consistent in both tables and text.

REFERENCES: References should be limited to those citations noted in the text, and kept to a minimum of 18. (A complete review of the literature is rarely desirable.) The references must be typed, doublespaced, and are to be numbered consecutively as they appear in the text, with their positions in the text indicated. An alphabetized bibliography is used only when the listing is of books suggested for supplementary reading.

All references must be checked for absolute accuracy. Each journal reference must include author(s) and initials, complete title ot article, name of publication, volume, first page of article, and date. Complete dates (month, day, and year) are to be included with all references that have appeared within the last three years. Include with book references name of author(s) and/or editor(s) with initials, title of book, edition, location, publisher, year, volume (if given), and page. If reference is to a chapter within a book, include the author of the chapter (if different from author of the book), and the title of the chapter, if any.

ILLUSTRATIONS: Authors are urged to use the services of professional illustrators and photographers when possible. Drawings and charts should always be done in black ink on white paper. Clear, glossy photographs, black on white, should be submitted and such illustrations numbered consecutively and their positions indicated in the text.

Magnifications will be modified in proportion to the amount of reduction necessary to fit the pages of the Journal. Please do not deface an illustration by writing on the front or the back, nor should it be taped or pasted to paper. The illustration may be pasted onto a piece of cardboard. Attached to the back of each illustration, chart or photograph should be the figure number, the author's name and the title of the article.

Legends for illustrations should be typewritten on a separate page with numbers corresponding to those on the photographs and drawings.

Recognizable photographs of patients are to be masked and should carry with them written permission for publication.

EDITORIAL RESPONSIBILITY: Manuscripts are subject to editorial modification and such revisions as are necessary to bring them into conformity with Journal style.

Statements made or opinions expressed by any contributor in any article or feature published in the Journal are the sole responsibility of the author.

PERMISSIONS: When material is reproduced from other sources, full credit must be given to both the author and publisher and written permission from these sources must be included when the material is submitted.

COPYRIGHT: Material that is published in the Maryland State Medical Journal is protected by copyright and may not be reproduced without the written permission of both the author and the Journal.

Whenever anxiety induces or intensifies clinical symptoms

Librium®
(chlordiazepoxide HCl)

Quickly relieves anxiety~Helps improve response in psychophysiologic disorders~Seldom impairs mental acuity or physical coordination,on proper dosage~ Has wide margin of safety

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Indicated when anxiety, tension and apprehension are significant components of the clinical profile.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving).Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral*—Adults: Mild and moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d. (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) Capsules, 5 mg, 10 mg and 25 mg—bottles of 50. Libritabs™ (chlordiazepoxide) Tablets, 5 mg, 10 mg and 25 mg—bottles of 100. With respect to clinical activity, capsules and tablets are indistinguishable.

THE JOINT COMMISSION ON ACCREDITATION OF HOSPITALS

has accredited

TAYLOR MANOR HOSPITAL

for 3 years

which has been surveyed and meets the standard for hospitals of The Joint Commission on Accreditation of Hospitals. For providing high quality medical and hospital care in all services and for maintaining as its primary objective the safety and welfare of the patient, this certificate of accreditation is granted by the authority of the Joint Commission on Accreditation of Hospitals.

It has been gratifying to know that the high standards we have always taken for granted have received national recognition on our first voluntary application.

You as a physician can now have added confidence in our continual efforts on your patients behalf.

he may be a candidate for

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg and Nystatin 500,000 units CAPSULE-SHAPED TABLETS Lederle

b.i.d.

guard susceptible patients against intestinal monilial overowth during broad-spectrum therapy—the protection of ystatin is combined with demethylchlortetracycline in ECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN the broad-spectrum therapy that prevents monilial ergrowth.

fectiveness: Because its antibacterial component is DECLOMYCIN emethylchlortetracycline, DECLOSTATIN should be equally or more ective therapeutically than other tetracyclines in infections caused by racycline-sensitive organisms. The antifungal component, Nystatin, otects against superinfection by antibiotic-resistant fungal overgrowth articularly monilia) in the intestinal tract.

ntraindication: History of hypersensitivity to demethylchlortetracyne or nystatin.

arning: In renal impairment, usual doses may lead to excessive accumation and liver toxicity. Under such conditions, lower than usual doses e indicated, and, if therapy is prolonged, serum level determinations ay be advisable. A photodynamic reaction to natural or artificial sunght has been observed. Small amounts of drug and short exposure may oduce an exaggerated sunburn reaction which may range from erytema to severe skin manifestations. In a smaller proportion, photoergic reactions have been reported. Patients should avoid direct posure to sunlight and discontinue drug at the first evidence of skin scomfort. Necessary subsequent courses of treatment with tetracynes should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Demethylchlortetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

Lederle

LEDERLE LABORATORIES
A Division of American Cyanamid Company, Pearl River, New York

It's almost as if you were there to give an injection of penicillin

V-Cillin K®, Pediatric dependable oral penicillin therapy

Potassium Phenoxymethyl Penicillin

Description: V-Cillin K, the potassium salt of V-Cillin® (phenoxymethyl penicillin, Lilly), combines acid stability with immediate solubility and rapid absorption. Higher, more rapid serum levels are obtained than with equal oral doses of penicillin G.

Indications: Streptococcus, pneumococcus, and gonococcus infections; infections caused by sensitive strains of staphylococci; prophylaxis of streptococcus infections in patients with a history of rheumatic fever; and prevention of bacterial endocarditis after tonsillectomy and tooth extraction in patients with a history of rheumatic fever or congenital heart disease.

Contraindication: Penicillin hypersensitivity.

Warnings: In rare instances, penicillin may cause acute anaphylaxis which may prove fatal unless promptly controlled. This type of reaction appears more frequently in patients with a history of sensitivity reactions to penicillin or with bronchial asthma or other allergies. Resuscitative drugs should be readily available. These include epinephrine and pressor drugs (as well as oxygen for inhalation) for immediate allergic manifestations and antihistamines and corticosteroids for delayed effects.

Precautions: Use cautiously, if at all, in a patient with a strongly positive history of allergy.

In prolonged therapy with penicillin, and particularly with high parenteral dosage schedules, frequent evaluation of the renal and hematopoietic systems is recommended.

In suspected staphylococcus infections, proper laboratory studies (including sensitivity tests) should be performed.

The use of penicillin may be associated with the overgrowth of penicillin-insensitive organisms. In such cases, discontinue administration and take appropriate measures.

Adverse Reactions: Although serious allergic reactions are much less common with oral penicillin than with intramuscular forms, manifestations of penicillin allergy may occur.

Penicillin is a substance of low toxicity, but it possesses a significant index of sensitization. The following hypersensitivity reactions have been reported: skin rashes ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; and reactions resembling serum sickness, including chills, fever, edema, arthralgia, and prostration. Severe and often fatal anaphylaxis has occurred (see Warnings). Hemolytic anemia, leukopenia, thrombocytopenia, and nephropathy are rarely observed side-effects and are usually associated with high parenteral dosage.

Administration and Dosage: Usual dosage range, 125 mg. (200,000 units) three times a day to 500 mg. (800,000 units) every four hours. For infants, 50 mg. per Kg. per day divided into three doses.

See package literature for detailed dosage instructions for prophylaxis of streptococcus infections, surgery, gonorrhea, and severe infections.

How Supplied: Tablets V-Cillin K® (Potassium Phenoxymethyl Penicillin Tablets, U.S.P.), 125 mg. (200,000 units), 250 mg. (400,000 units), and 500 mg. (800,000 units).

V-Cillin K® (potassium phenoxymethyl penicillin, Lilly), Pediatric, for Oral Solution, 125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc. of solution (approximately one teaspoonful). [042567A]

UNION PAY SCALE COMPARISON

It was brought to our attention recently that an appliance repair man charged $12 for a house visit. Parts to effect a repair totalled another $17, making a total charge of $29; somewhat more than the physician makes for a house call.

Spurred by this comparison, we present below the rates and the totals for varying work weeks that skilled tradesmen receive:

Carpenters, $4.82 per hour, union rate

Electricians, $5.45 per hour, union rate

Plumbers, $5.21 per hour, union rate

Linotype Operators, $4.50 per hour, union rate

Bricklayers, $5.80 per hour, union rate, including fringe benefits

Based on time and a half for every hour over 40 hours, the weekly wage would be: (Linotype workers have a 36 hour, 40 minute basic work week):

	ANNUAL WAGE		
	40 hours	60 hours	80 hours
Carpenters	10,025	17,544	25,063
Electricians	11,336	19,843	28,350
Plumbers	10,837	18,970	27,103
Linotype Oprs.	9,750	16,770	23,790
Bricklayers	11,232	19,656	28,080

In larger cities than Baltimore, such as New York, basic hourly wage rates are comparatively higher.

According to the latest Medical Economics Survey, the average physician works anywhere from 60, 70 to 80 hours per week.

PALM AND TURN CONTAINER

Information has been received from the Maryland Poison Control Center that a new "Palm and Turn" container has been on the market for over a year.

Physicians are urged to ask pharmacists to use this type of container as it is felt that routine use would prevent many toxic ingestions by children.

REFERENCE COMMITTEE MEETING

The Reference Committee will meet on

THURSDAY, MARCH 20, 1969

at 8:00 p.m., in the Faculty building, at which time any resolutions for consideration by the Annual Session of the House of Delegates will be discussed. All members in good standing are invited to attend this session.

MED-CHI RETIREMENT FUND

The net asset value of the Med-Chi Members Retirement Fund has increased 22.05% for the period January 1, 1968, through November 31, 1968.

PUBLIC SPEAKING COURSE

A one-day public speaking course will be held under the auspices of the Public Relations Committee of the Faculty on Thursday, March 13, 1969, from 9:00 a.m. to 5:00 p.m. Registration is limited and those interested should contact the Faculty office promptly to indicate their wish to attend.

CONGRESS ON SOCIOECONOMICS OF HEALTH CARE

The third national Congress on the Socioeconomics of Health Care has been scheduled for March 28 and 29, at the Palmer House, Chicago, Illinois. Full details may be obtained from the AMA or the Faculty office.

LEGISLATIVE NOTE

Three bills in which the Faculty has more than usual interest have been assigned numbers by the General Assembly. House Bill 27 is the Revised Medical Practice Act; Senate Bill 75 is the Implied Warranty Proposal that would define blood transfusion as a service rather than a product; and Senate Bill 149 provides for the Incorporation of Self-Employed Persons. The latter two bills have been referred to the Senate's Economic Affairs Committee, while HB 27 has been referred to the House Judiciary Committee.

Those physicians wishing to testify in behalf of any of these bills should contact the Faculty office for hearing dates and times.

DIA-QUEL actually tastes good

DIA-quel contains the only therapeutically active ingredient of paregoric—tincture of opium. This has been combined with homatropine methylbromide and pectin to make a sensible antidiarrheal formula.

By leaving out paregoric's outdated preservative—bitter-tasting camphor—we've produced an antidiarrheal that is good-tasting, as well as effective and prompt-acting in acute, nonspecific diarrheas and their accompanying "cramps." It is DIA-quel, a clear, red liquid with a pleasant cherry flavor.

Each teaspoonful (5 ml.) of DIA-quel Liquid contains:
Tincture of Opium... 0.03 ml.—Equivalent to 0.75 ml. of paregoric.
(Warning: May be habit forming)
To reduce hypermotility and frequency.
Homatropine Methylbromide... 0.15 mg.
A safe dose for mild spasmolysis to curb cramping and griping.
Pectin... 24. mg.
Demulcent, adsorbent. Helps form stools.
Alcohol 10% by volume.

n case you're curious, back in the 1700's paregoric was eing used for diarrhea, but since the state of the pharmaeutical art was extremely primitive, fungus growth in ne medication was a problem. Bitter-tasting camphor as added to prevent such growth and anise oil was dded in an attempt to cover up the camphor taste. DIA-quel Liquid is a modern formulation that does not ontain either of these outdated ingredients.

Caution: With use of DIA-quel Liquid observe the usual precautions associated with opium derivatives and anticholinergics.

Dosage: Usual adult dosage: 1 or 2 tablespoonfuls (15 r 30 ml.) t.i.d. or q.i.d. Usual children's dosage (Clark's ule): ½ to 2 teaspoonfuls (2.5 to 10 ml.) t.i.d. or q.i.d.

How Supplied: In 4 fl. oz. (118 ml.) band-sealed bottles.

DIA-quel is a Federally exempt narcotic (Class X) preparation. Where state law permits, no prescription is necessary.

For a complimentary sample of DIA-quel, simply mail your request to us on a signed prescription blank.

Computer Death Predictions

Help Reduce Hospital Deaths

Physicians at Pacific State Hospital use a computer to ascertain which ones among their patients run a relatively high risk of death in the early months after admission—and have found these projections help to prevent death.

Patients entering the hospital, which is dedicated exclusively to the treatment of the mentally retarded, are tested and data about them is set up on permanent files in a computer system. As the files began to build, physicians noted that patients with certain characteristics were more likely to die while hospitalized than others, especially within the first few months after admission.

A computer program was developed to study the several variables—age, sex, intelligence quotient, type of illness—to determine which patients ran a high death risk. The computer found the highest risk was among children under five years of age with IQ's of less than 30. (Normal IQ is 100). The findings were that 13% of these children died within six months of admission and that 20% died within four years.

"We believe one of the causes of this may have been the shock these children experienced in being taken from the atmosphere of the home and being placed in the hospital—coupled with the fact that their physical condition usually is somewhat poor," said Richard K. Eyman, PhD, a psychologist and director of computer operations at the hospital.

"When we began this study, we found 133 per thousand of these young, low-IQ children were dying within six months of admission," Dr. Eyman said. "With the computer's help, we reduced this figure to 23 per thousand in ten years by sending these projections to the hospital staff.

Dr. Eyman said computerized death predictions could be applied to hospitals other than those that handle the mentally retarded.

"The great advantage of the computer is that it does not miss anything. In the course of admitting patients, a human could miss a relationship between certain symptoms. But the computer will not—if it has been properly programmed," he said.

Dr. Eyman is director of the Socio-Behavioral Study Center for Mental Retardation at the hospital. He directs a variety of computer-oriented research projects into mental retardation with a $3-million, seven-year grant from the National Institute of Mental Health.

The computer keeps records on 13,000 patients —all those who have entered the hospital since its founding in 1927. The present patient population is 2,800—ranging from infants to the elderly.

the thousandth teaspoonful

Peptic ulcer patients find the thousandth dose of this antacid as effective and easy-to-take as the first!

Optimal neutralization[1] — provided by the combination of aluminum and magnesium hydroxides.

Unfailing good taste — confirmed by 87.5% of 104 patients in one study, after a total of 20,459 documented days on Mylanta Liquid or tablets.[2]

Concomitant relief of G. I. gas distress — provided by the proven antiflatulent action of simethicone[3].

Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth); one or two teaspoonsful to be taken between meals and at bedtime, or as directed by physician.

"Man's best friend" in wintertime diarrheas

In winter "flu" and viral gastroenteritis, Donnagel (4 oz. size!) can bring aid and comfort to sufferers from both diarrhea and its discomforts because it contains kaolin and pectin plus belladonna alkaloids (as in Donnatal®). Donnagel treats the whole diarrhea problem. Available on your prescription or recommendation. A. H. Robins Company, Richmond, Va. 23220

A·H·ROBINS

CLEAR THE TRACT!
ROBITUSSIN®

THERE'S A FORMULATION FOR EVERY COUGHING NEED

All five members of the Robitussin family contain glyceryl guaiacolate. This outstanding expectorant agent increases the output of lower respiratory tract fluid (R.T.F.) Increased R.T.F. volume thins mucus, thereby improving the action of bronchial and tracheal cilia and making thick, inspissated mucus less viscid and easier to raise.

For coughs of colds and "flu"

ROBITUSSIN®
Each 5 cc. contains:
Glyceryl guaiacolate ..... 100 mg.
Alcohol, 3.5%

For unproductive, allergic coughs

ROBITUSSIN A-C® (exempt narcotic)
Each 5 cc. contains:
Glyceryl guaiacolate ..... 100 mg.
Pheniramine maleate ..... 7.5 mg.
Codeine phosphate ..... 10.0 mg.
(warning: may be habit forming)
Alcohol, 3.5%

Non-narcotic for 6-8 hour cough control

ROBITUSSIN-DM®
Each 5 cc. contains:
Glyceryl guaiacolate ..... 100 mg.
Dextromethorphan hydrobromide .... 15.0 mg.
Alcohol, 1.4%

Robitussin-DM in solid form for "coughs on the go"

COUGH CALMERS™
Each Cough Calmer contains:
Glyceryl guaiacolate ..... 50 mg.
Dextromethorphan hydrobromide .. 7.5 mg.

Clears sinuses and nasal stuffiness as it relieves cough

ROBITUSSIN-PE®
Each 5 cc. contains:
Glyceryl quaiacolate ..... 100 mg.
Phenylephrine hydrochloride ..... 10.0 mg.
Alcohol, 1.4%

171st Annual Meeting

More prominent speakers * who will present papers during the Annual Meeting in April include Denton A. Cooley, MD, and George D. Zuidema, MD.

Denton A. Cooley, MD, world-renowned heart surgeon, will speak on *Experiences with Cardiac Transplantation in Man* during the Annual Meeting of the Medical and Chirurgical Faculty on Thursday, **April 10,** at the Alcazar in Baltimore.

Dr. Cooley

Dr. Cooley, who was born in Houston, was graduated from the University of Texas and in 1944 received his MD degree from The Johns Hopkins University School of Medicine. He served a surgical internship and residency at the Hopkins, followed by a year as senior surgical registrar in thoracic surgery at Brompton Hospital for Chest Diseases in London.

A member of the Board of Governors of the American College of Surgeons, the Board of Thoracic Surgery and the Board of Regents of the American College of Chest Physicians, Dr. Cooley is currently professor of surgery at Baylor University College of Medicine, chief of cardiovascular surgery at St. Luke's Episcopal Texas Children's Hospital, physician-in-chief of the Texas Heart Institute, attending surgeon at the Methodist Hospital and the Ben Taub General Hospital in Houston, and consultant in cardiovascular surgery at several Veterans Administration Hospitals in Texas.

Among the over 20 honors and awards which have been bestowed on Dr. Cooley are:

Ten Outstanding Young Men in the United States—U.S. Jr. Chamber of Commerce

Humanitarian Award—Variety Clubs International

Distinguished Alumnus Award—University of Texas

Rene Leriche Prize (for the most significant contribution to cardiovascular surgery)—International Surgical Society

Distinguished Achievement Award—*Modern Medicine*

Surgical Grand Rounds will be presented at the Alcazar on Thursday afternoon, **April 10,** by **George D. Zuidema, MD,** and the **surgical staff of The Johns Hopkins.** Dr. Zuidema since 1964 has been professor and director, department of surgery, The Johns Hopkins University School of Medicine, and surgeon-in-chief, The Johns Hopkins Hospital.

Dr. Zuidema

After receiving his MD at The Johns Hopkins in 1953, he served a straight surgical internship, an assistant residency in surgery, and was chief resident surgeon at the Massachusetts General Hospital. In 1959, Dr. Zuidema was a teaching fellow in surgery at Harvard Medical School. Following this he was assistant professor, then associate professor of surgery at the University of Michigan Medical School until 1964 when he came to Baltimore. Dr. Zuidema has held, and still holds, many consultant appointments among which are membership on the Science and Technology Advisory Committee and the Medical Advisory Council for manned space flight, and editor of the *Journal of Surgical Research.* The awards and scholarships received by him, and the society memberships and visiting professorships, are too numerous to list.

* See the December and January Journals for capsule biographies of **Robert L. Evans, MD, Howard W. Jones, Jr., MD, Milton Helpern, MD,** and **Joseph Lee Hollander, MD,** who also will be featured during the scientific sessions of Annual Meeting in April.

G.I. BLEEDING

Marvin M. Schuster, MD
Assistant Professor of Medicine
The Johns Hopkins University School of Medicine, and
Assistant Chief of Medicine,
Baltimore City Hospitals

A practical approach to the diagnosis and treatment of gastrointestinal hemorrhage will be discussed. This will include both the acute massive bleed as well as chronic hemorrhage and will emphasize diagnostic technicalities which have been found useful.

Sponsor: Easton Memorial Hospital
Replays: Monday, March 10, 1969 12:30 P.M.
Wednesday, March 12, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

MARCH 14, 1969—12:30 P.M.

THE PATIENT WITH DIARRHEA— MALABSORPTION SYNDROME

Vernon M. Smith, MD
Professor of Clinical Medicine and Head
Department of Medicine,
Mercy Hospital

Diarrhea is a common disorder which usually is benign, self-limited and requires no treatment. Persistent diarrhea, on the other hand, may denote important underlying disease, including malabsorption. The talk will be directed toward a logical distinction among the malabsorption syndromes, according to their underlying pathophysiological states; and toward the practical management of patients suspected of having malabsorption syndrome.

Sponsor: Prince George's General Hospital
Replays: Monday, March 17, 1969 12:30 P.M.
Wednesday, March 19, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

MARCH 21, 1969—12:30 P.M.

ABDOMINAL PAIN

David Skinner, MD

Assistant Professor of Surgery
The Johns Hopkins University School of Medicine

The differential diagnosis of upper abdominal pain includes common conditions such as hiatal hernia, ulcer, pancreatitis, pancreatic carcinoma, biliary tract disorders, aortic aneurysms, and ischemic mesenteric vascular disease. Physiologic and radiographic tests useful in establishing specific diagnoses will be described, and indications for surgical or medical treatment will be presented.

Sponsor: Cumberland Memorial Hospital

Dear Doctor, You made me what I am today — a whole lot slimmer!

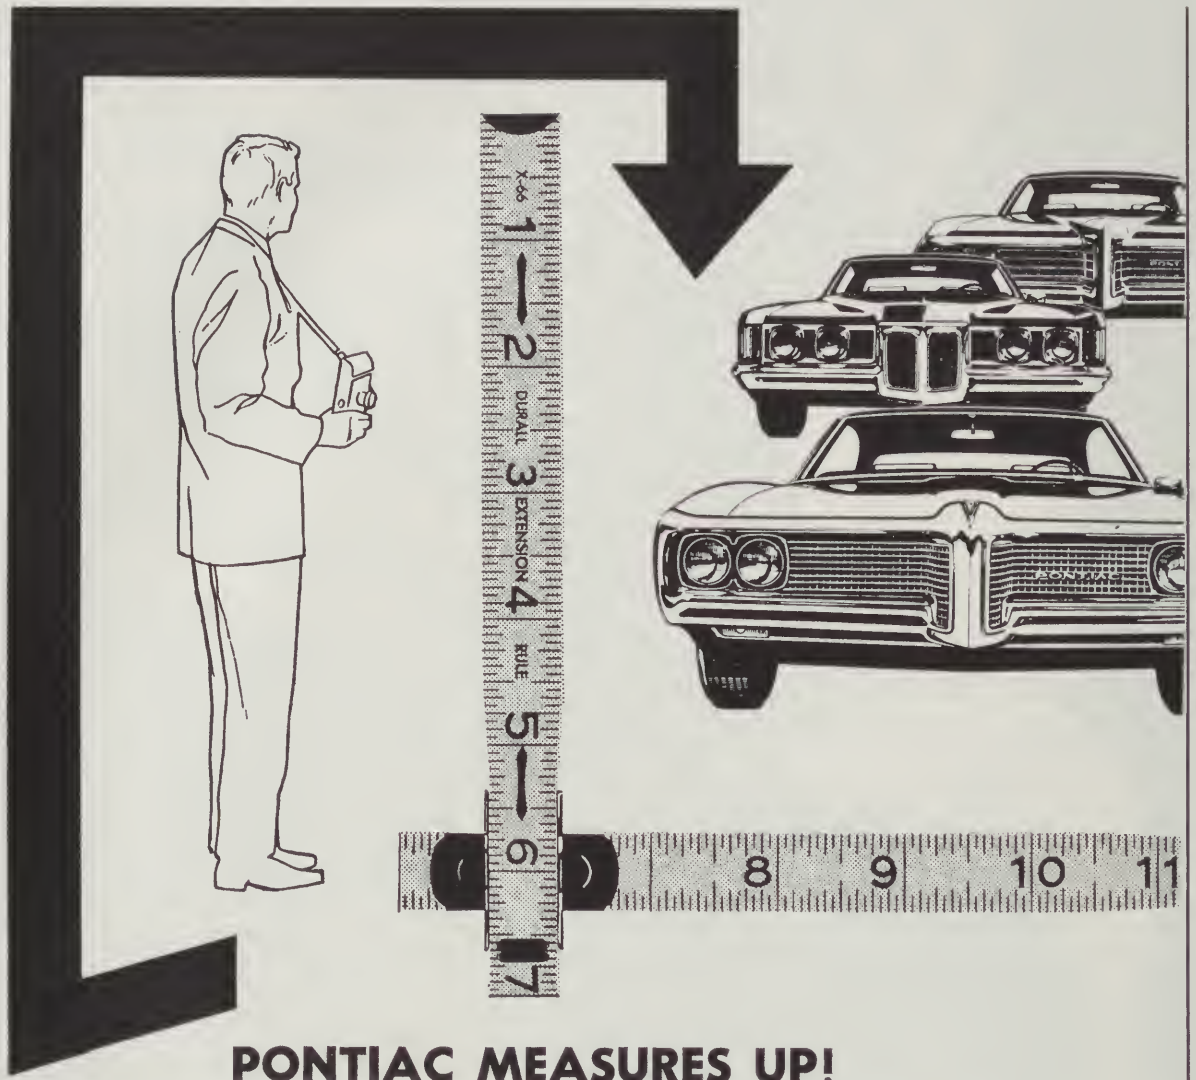
TEPANIL —the right start in support of the weight-control program *you* recommend. It reduces the appetite. Doesn't kill it. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation. Because TEPANIL works on the appetite, not on the "nerves."

Contraindications: Contraindicoted concurrently with MAO inhibitors, in potients hypersensitive to diethylpropion hydrochloride, ond in emotionally unstoble patients known to be susceptible to drug obuse.

Warning: Although generally sofer thon the omphetomines, use greot coution when prescribing for potients with severe hypertension or severe cardiovosculor diseose. Should not be used during the first trimester of pregnoncy unless potentiol benefits outweigh potentiol risks.

Side Effects: While rorely cousing theropy to be withdrown, side effects moy occur occosionolly; CNS effects (such as insomnio, nervousness, jitteriness), dryness of mouth, thirst, nausea, abdominal distress, constipotion, headoche, ollergic response including urticario or other dermatitis; rarely ossociated with tochycordio, cordioc orrhythmio or ECG chonges.

Convenience of two dosage forms: TEPANIL Ten-tab toblets: One 75 mg. tablet daily, swallowed whole, in midmorning (10 o.m.); TEPANIL: One 25 mg. tablet three times daily, one hour before meols. If desired, on additionol tablet moy be given in midevening to overcome night hunger.



Use in children under 12 years of age is not recommended.

THE MONTH IN WASHINGTON

A House Ways and Means Committee member introduced on the first day of the new Congress a bill that would provide federal income tax credits to help individuals buy private health insurance.

The legislation (HR 19), sponsored by Rep. Richard Fulton (D., Tenn.), was similar in principle to a health insurance financing plan utilizing tax credits approved by the American Medical Association House of Delegates at San Francisco last June and reaffirmed at Miami Beach last December.

"Certainly before expanding any federal program, I believe it worthwhile to explore the use of the private sector and our tax system," Fulton said.

The Fulton bill provides that individuals with incomes of $2,500 or less and families with incomes of $5,000 or less would receive $150 vouchers from the federal government per eligible individual for the purchase of health insurance. The family maximum would be $400.

In the case of a taxpayer with an income between $2,500.01 and $5,000, or a family with an income between $5,000.01 and $7,500, the credit would be 75% per eligible individual with a maximum of $400 per family.

In the case of a taxpayer with an income of $5,000.01 to $7,500, or a family with an income between $7,500.01 and $10,000, the credit would be 50% per eligible individual with a $400 family maximum.

In the case of a taxpayer with an income exceeding $7,500.01, or a family with an income exceeding $10,000.01, the credit would be 25%.

At San Francisco, the House of Delegates adopted as approved AMA policy "the principle of graduated income tax credits for premiums paid for adequate health insurance." A resolution adopted at Miami Beach called upon the AMA to "vigorously promote the enactment of federal legislation implementing" the plan.

* * *

A special commission on health facilities concluded that government and private enterprise must cooperate to organize the nation's health resources into effective, efficient and economical community systems of comprehensive health care for all persons.

The National Advisory Commission on Health Facilities, established in October, 1967, drafted its report to the President in general terms and did not make any recommendations for legislation.

James Z. Appel, MD, a former president of the American Medical Association and a commission member, said the family physician would be the ideal "point of entry" to a community health system but there are not enough of them.

A summary of the report included:

"America's health care systems should combine private and public responsibility. Facilities and systems will vary from community to community in accordance with local capacities and local needs, but guiding principles should govern the effort to develop effective and efficient health care systems:

- These systems should be organized to assure appropriate points of entry into, and continuity of health care services.
- Every citizen should have ready access to quality health care.
- States, regions, local communities, and all health institutions should carry out continuous planning.
- Both those who provide and consume health services should participate in the decisions.
- All levels of health care should be interdependent."

* * *

A Health, Education and Welfare Department report to Congress recommended that preventive health care services not be added to medicare benefits at this time.

The report cited as reasons for the negative recommendation: administrative constraints, inability to estimate costs, limited experience with automated multi-phasic health screening, and an inadequate supply of health professionals.

The report was one of three requested by Congress last year and submitted before the change in Administration.

A second report dealt with coverage of mentally ill under medicare but did not include any recommendations.

The third reviewed qualifications of personnel under current medicare regulations. It stated that, because of an acute

manpower shortage in the field, physical therapists should be considered qualified if they could establish an adequate level of competency. HEW is developing a proficiency examination.

HEW recommended against allowing licensed practical nurses to serve as nurses responsible for the total nursing care at an extended care facility. It also recommended against changes in the regulations that set minimal standards for independent laboratory personnel.

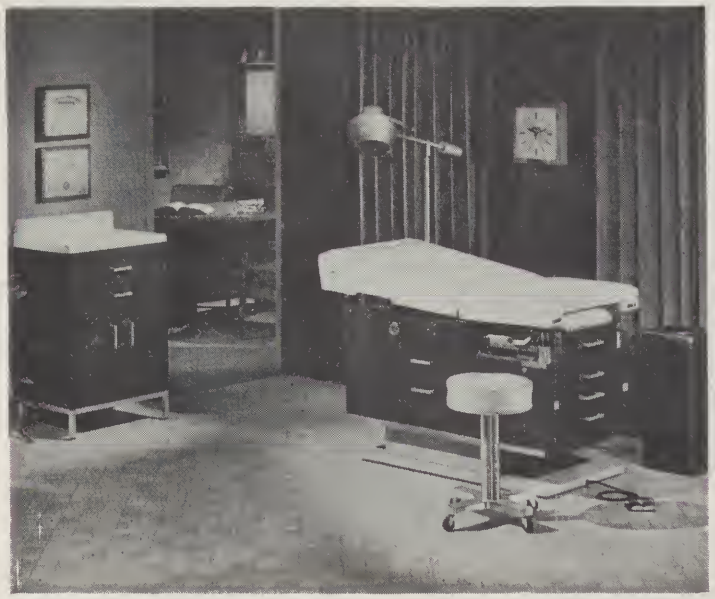
* * *

The premium rate for medicare supplementary insurance covering physicians' fees (Plan B) will remain at the present rate, $4 each for the individual beneficiary and the federal government, until July 1, 1970.

The Johnson Administration's Secretary of Health, Education and Welfare, Wilbur J. Cohen, decided against an increase although the Social Security Administration's chief actuary had advised that an anticipated rise in physicians' fees called for an increase of 40 cents each for the beneficiary and the government.

Cohen again asked physicians to show "unusual restraint" in setting fees. He urged that physicians and patients cooperate "in eliminating unnecessary utilization of physicians' services," and asked carriers and intermediaries to carefully review claims during the next 18 months.

* * *



The Food and Drug Administration proposed that six widely prescribed antibiotic drug combinations be taken off the market on grounds that they fail to live up to their claims of effectiveness.

The drugs and their manufacturers: Albamycin G. U., Albamycin-T capsules and granules, and Panalba capsules, granules and drops—Upjohn Co.; Achromycin nasal suspension—Lederle Laboratories; Mysteclin F capsules, syrup and pediatric drops and Mysteclin F-125 capsules—E. R. Squibb & Sons Inc.

The drug companies were given 30 days to respond before FDA's final action. The FDA order could be appealed to the courts.

Two of the drug companies promptly protested the FDA proposal in public comments. An Upjohn spokesman said his company's combinations are superior to the major constituents alone. A Squibb spokesman said Mysteclin F had wide acceptance among physicians and a proper place in medical practice. A Lederle spokesman said Achromycin was not a major sales product, and declined to comment on what the company's official response would be.

CREATE THE PROPER PROFESSIONAL IMAGE

Hot under the collar...

high under the cuff.

Sometimes
he forgets he has hypertension, gets hot under the collar...high under the cuff.

For such patients, consider **Regroton®**

chlorthalidone	50 mg.
reserpine U.S.P.	0.25 mg.

To lower blood pressure
and allay anxiety in hypertension.

For brief summary of prescribing information, see next page.

RE-6392

Regroton®

Geigy

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

the once-a-day tablet for anxious hypertensives

Regroton is a combination of two basic antihypertensives designed to lower blood pressure and allay anxiety in hypertension. With Regroton he can keep his shirt on and you can keep his blood pressure down.

Before prescribing, please review carefully the indications, contraindications, warning, precautions, adverse reactions and dosage information below.

Regroton®
Each tablet contains:
chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

Indications: Hypertension.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs.
Use in pregnancy: Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. Increased respiratory secretions, nasal congestion, cyanosis and anorexia may occur in infants born to reserpine-treated mothers.
Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue therapy with this agent two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.
Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Severe salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients.
Adverse Reactions: The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible.
Average Dosage: One tablet daily with breakfast.
Availability: Pink, single-scored tablets in bottles of 100 and 1000.
(B)46-600-C

hanks to

Butisol SODIUM®

SODIUM BUTABARBITAL)

he "daytime sedative" for everyday situational stress

/hen stress is situational—environmental pressure, orry over illness—the treatment often calls for an nxiety-allaying agent which has a prompt and redictable calming action and is remarkably well olerated. BUTISOL SODIUM (sodium butabarbital) eets this therapeutic need.

fter 30 years of clinical use . . . still a first choice mong many physicians for dependability, safety and conomy in mild to moderate anxiety.

Contraindications: Porphyria or sensitivity to arbiturates.

Precautions: Exercise caution in moderate to severe epatic disease. Elderly or debilitated patients may eact with marked excitement or depression.

Adverse Reactions: Drowsiness at daytime sedative ose levels, skin rashes, "hangover" and systemic isturbances are seldom seen.

Warning: May be habit forming.

Usual Adult Dosage: As a daytime sedative, 5 mg. (¼ gr.) to 30 mg. (½ gr.) t.i.d. or q.i.d.

vailable for daytime sedation: Tablets, 15 mg. (¼ gr.), 0 mg. (½ gr.); Elixir, 30 mg. per 5 cc. (alcohol 7%). BUTICAPS® [Capsules BUTISOL SODIUM (sodium butabarbital)] 5 mg. (¼ gr.), 30 mg. (½ gr.).

McNEIL

IcNeil Laboratories, Inc., Fort Washington, Pa.

In childhood

Warnings: Lomotil should be used with caution in patients taking barbiturates and with caution, if not contraindicated, in patients with cirrhosis, advanced liver disease or impaired liver function.

Precautions: Lomotil is a Federally exempt narcotic with theoretically possible addictive potential at high dosage; this is not ordinarily a clinical problem. Use Lomotil with considerable caution in patients receiving addicting drugs. Recommended dosages should not be exceeded, and medication should be kept out of reach of children. Should accidental overdosage occur, signs may include severe respiratory depression, flushing, lethargy or coma, hypotonic reflexes, nystagmus, pinpoint pupils, tachycardia; continuous observation is necessary.

Adverse Reactions: Side effects reported with Lomotil therapy include nausea, sedation, dizziness, vomiting, pruritus, restlessness, abdominal discomfort, headache, angioneurotic edema, giant urticaria, lethargy, anorexia, numbness of the extremities, atropine effects, swelling of the gums, euphoria, depression and malaise. Respiratory depression and coma may occur with overdosage.

Dosage: The recommended initial daily dosages, given in divided doses until diarrhea is controlled, are as follows:

diarrheas...

- careful supervision
- electrolyte replacement
- specific anti-infective therapy

and...

LOMOTIL®

TABLETS/LIQUID

Each tablet and each 5 cc. of liquid contains:
diphenoxylate hydrochloride ..... 2.5 mg.
(Warning: May be habit forming)
atropine sulfate .....0.025 mg.

LOMOTIL, in conjunction with specifically indicated medical management, may be lifesaving in children with severe diarrhea.

Lomotil lowers the excessive intestinal propulsion characteristic of diarrhea. This reduction of precipitate intestinal flow allows a normal or more nearly normal reabsorption of fluid and electrolytes and counteracts the dehydration so hazardous to children.

Moreover, eight years' experience has demonstrated that Lomotil controls diarrhea with a minimum of unwanted secondary actions.

Senra del Valle and his associates[1] conducted a study of 477 children with diarrhea, most of whom were hospitalized with the disorder. Lomotil, used in 407 of the children, shortened the duration of the diarrhea.

Grinszpan, Goldstein and Divito[2] used Lomotil in 20 children with diarrhea and also reported a prompt disappearance of diarrhea. Harris and Beveridge[3] in a double-blind study of 50 children with diarrhea, however, found no clear pattern to suggest that Lomotil influenced the course of the condition.

Michener, Brown and Turnbull[4] added evidence supporting the beneficial effects of Lomotil in 80 children, concluding that Lomotil was highly useful in controlling abdominal cramping, diarrhea and hypermotility.

ıildren: Total Daily Dosage

3-6 mo. . . . ½ tsp.* t.i.d. (3 mg.)
6-12 mo. . . ½ tsp. q.i.d. (4 mg.)
1-2 yr. . . . . ½ tsp. 5 times daily (5 mg.)
2-5 yr. . . . . 1 tsp. t.i.d. (6 mg.)
5-8 yr. . . . . 1 tsp. q.i.d. (8 mg.)
8-12 yr. . . . 1 tsp. 5 times daily (10 mg.)
dults: . . . . 2 tsp. 5 times daily (20 mg.) or 2 tablets q.i.d.

ısed on 4 cc. per teaspoonful.

Maintenance dosage may be as low ıs one-fourth the initial daily dosage.

THE BETTMAN ARCHIVE

Just one tablet at bedtime • Prevents painful night leg cramps • Permits restful sleep

How many of your patients stamp their feet at night and lose sleep because of painful leg cramps? Unless prompted, they usually fail to report this distressing condition and suffer needlessly.

One tablet of QUINAMM at bedtime usually controls distressing night cramps and permits restful sleep with the initial dose.

Prescribing information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Side Effects/Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

tones down the "explosive gut"

helps restore normal motility and tone

CANTIL®

(mepenzolate bromide)

Diarrhea and other symptoms of common G.I. disorders can often be curbed with Cantil (mepenzolate bromide), bringing welcome relief to the harassed patient. Relatively specific for the hyperactive colon, it helps reduce diarrhea, pain and spasm with minimal effect on other viscera. Cantil (mepenzolate bromide) is indicated whenever these symptoms are associated with irritable colon, gastroenteritis, diverticulitis, and mild to moderate ulcerative colitis.

It is an anticholinergic drug without narcotic properties. Side effects are usually mild.

LAKESIDE

CONTRAINOICATIONS: Sensitivity to Cantil® (mepenzolate bromide), glaucoma, G.I. or G.U. obstruction, toxic megacolon. WARNINGS: Possibility of adverse reactions in advanced severe ulcerative colitis and atypical agitated reactions to phenobarbital in the elderly (Cantil with Phenobarbital). PRECAUTIONS: Cantil is of adjunctive use only; treatment of the underlying condition is indicated, be it organic or functional. Observe caution in conditions known to be incompatible with atropine-like drugs, e.g., open-angle glaucoma or prostatic hypertrophy. ADVERSE EFFECTS: Dry mouth; blurred vision; constipation; nausea; vomiting; bloating; dizziness; urinary retention. All are anticholinergic effects and usually tolerable. Habituation and idiosyncratic reactions to phenobarbital (Cantil with Phenobarbital) are possible, as is generalized rash. DOSAGE: One or two tablets three times a day and one or two at bedtime usually provide prompt relief. Cantil with Phenobarbital may be prescribed if sedation is required. HOW SUPPLIED: CANTIL (mepenzolate bromide)—25 mg. per scored tablet. Bottles of 100 and 250. CANTIL with PHENOBARBITAL—containing in each scored tablet 16 mg. phenobarbital (warning: may be habit forming) and 25 mg. mepenzolate bromide. Bottles of 100 and 250.

MEDICAL NEWS

During the rededication ceremony, marking the 20th anniversary of the "Your Family Doctor" television series on WMAR-TV, the station's assistant general manager, Robert B. Cochrane, received a plaque in gratitude for WMAR-TV's ". . . 20 years of Public Education in Preventive Medicine, Public Health and Safety on the Weekly TV Series. . . ." On hand for the commemoration program entitled "Souvenirs of 20 Years" were representatives of the Baltimore City Health Department and the Medical and Chirurgical Faculty of Maryland. From left to right the participants are: Jack Redfern, Chief of Community Health Information in the Baltimore City Health Department, who appears weekly as Dr. John Worthington in the series; Huntington Williams, MD, former Commissioner of Health, who helped inaugurate the program in 1948; Arthur G. Siwinski, MD, President of the Faculty, Robert E. Farber, MD, Commissioner of Health of Baltimore City; Emerson R. Julian, MD, chairman of the Health Committee of the Baltimore City Council, who represented the Mayor in presenting the plaque, and Mr. Cochrane.

* * *

Mary Ellen Avery, MD, Associate Professor of Pediatrics, The Johns Hopkins University School of Medicine, has been appointed Professor and Chairman of the Department of Pediatrics, Faculty of Medicine, McGill University, and Physician-in-Chief of the Montreal Children's Hospital.

Dr. Avery will assume her duties June 1, 1969, and will succeed Alan Ross, MD, who is retiring to become Founding Professor of Pediatrics at the new Medical School of University College, Nairobi, Kenya.

A 1952 graduate of The Johns Hopkins University School of Medicine, Dr. Avery is presently Pediatrician-in-Charge of the Newborn Nurseries at The Johns Hopkins Hospital.

* * *

Frederick M. Zerzavy, MD, a Fellow of the American College of Obstetrics and Gynecology, was recently appointed medical director of the outpatient department at Mount Sinai Hospital Medical Center in Chicago, and Associate Professor of Community Medicine and Assistant Professor of Obstetrics and Gynecology at the Chicago Medical School.

Dr. Zerzavy recently returned from a tour of duty in Viet Nam under the AMA's Volunteer Physicians Program.

* * *

The Sinai Hospital medical staff has elected the following officers for 1969: **Jerome Coller, MD,** attending physician in the Department of Medicine, is president; **Harold Sussman, MD,** a member of the Department of Surgery, vice-president; and **Sheppard Kaplow, MD,** of the Department of Anesthesiology, secretary-treasurer.

* * *

Paul Joliet, MD, Washington County Health Officer, recently became a member of the Faculty's subcommittee on Traffic Safety. He is also a member of the AMA Commission on Emergency Medical Services.

* * *

The newly elected president of the Medical Staff of Maryland General Hospital is **Charles E. Shaw, MD.** He succeeds **Stanley Bociek, MD,** who held the post last year.

Lloyd E. Saylor, MD, was elected vice-president and **Francis A. Clark, Jr., MD,** was re-elected secretary. **John W. Barnaby, MD,** re-elected treasurer, was presented a citation for his "devoted and exemplary" service to the hospital.

Four new members added to the executive committee are **William H. Mosberg, Jr., MD, L. Kemper Owens, MD, Edward S. Klohr, Jr., MD,** and **Frank P. Dwyer, Jr., MD.**

* * *

Carl Behm, associate administrator of South Baltimore General Hospital since 1962, has been appointed director of administration, succeeding **Donald T. Mills,** who retired recently.

Associated with the hospital since 1947, Mr. Behm has been principally responsible for the coordination of planning for the recently opened hospital building.

* * *

The Baltimore Area Council on Alcoholism has announced that its information and referral services, conducted up to now in Baltimore city only, will be open to county residents during this year.

". . . in this way, the public as well as the sufferers from this disease can be educated and treated," according to **Harry F. Klincfelter, MD,** vice president of the council.

* * *

Irene Hitchman, MD, Baltimore, has been named Deputy Commissioner of the Maryland Department of Mental Hygiene.

In 1941, Dr. Hitchman joined the staff of Springfield State Hospital, where she was staff psychiatrist and then clinical director. In 1962 she became director of hospital inspection and licensing for the state.

* * *

D. M. Ivey, MD, who has been a resident in ophthalmology in the Mayo Graduate School of Medicine, University of Minnesota at Rochester, has relocated at Andrews Air Force Base.

* * *

Marylanders named to various AMA Committees, Councils, etc. include **John J. Curry, MD,** of Silver Spring, reappointed to the Council on Drugs; **Albert I. Mendeloff, MD,** Baltimore, reappointed to the Drug Utilization Panel on Gastroenterology; **Robert A. Bier, MD,** Washington, reappointed consultant to the Council on National Security; **Abraham J. Mirkin, MD,** Cumberland, reappointed to the Committee on Medical Aspects of Automotive Safety; **Harry M. Robinson, Jr., MD,** reappointed to the Subcommittee on Skin, Committee on Rating of Mental and Physical Impairments.

Others reappointed are **Edmond J. McDonnell, MD,** Baltimore, alternate representative on the Interspecialty Committee from the American Academy of Orthopedic Surgeons; **William J. Peeples, MD,** Baltimore, alternate representative on the Interspecialty Committee, American Association of Public Health Physicians; and **Russell S. Fisher, MD,** Baltimore, Liaison Committee with the American Bar Association.

* * *

Andre Fesus, MD, and **Celeste Woodward, MD,** have just returned from 60-day tours of duty with the AMA Volunteer Physicians in Viet Nam.

* * *

Two NIH scientists have won the Prix André-Lichtwitz, a newly established French award for biological research in the area of phosphorus-calcium metabolism. **Gerald D. Aurbach, MD,** Chief of the Mineral Metabolism Section of the Metabolic Diseases Branch of the National Institute of Arthritis and Metabolic Diseases and **John T. Potts, MD,** former Chief of the Section on Polypeptide Hormones of the Molecular Disease Branch of the National Heart Institute shared the $1,000 award.

The prize is awarded to a scientist or a team of researchers for outstanding studies on calcium and phosphorus metabolism, either in the field of clinical or experimental biology or in the field of basic science. Drs. Aurbach and Potts are the first recipients of the award created under the auspices of the French National Institute for Health and Medical Research.

The two investigators have been in close collaboration on

problems of parathyroid physiology since 1962 at NIH. Since last August, Dr. Potts has been head of the Endocrine Unit at the Massachusetts General Hospital and Assistant Professor of Medicine at Harvard University.

* * *

Two key staff appointments were recently announced by **Stanley F. Yolles, MD,** director of the National Institute of Mental Health, in a move to emphasize Institute grants programs in the behavioral sciences.

Eli A. Rubinstein, PhD, is in the newly created post of Assistant Director of Extramural Programs and Behavioral Sciences, and **Raymond J. Balester, PhD,** is Dr. Rubinstein's Deputy.

Dr. Yolles said the new appointees, both of whom have been with NIMH for several years, will have dual responsibilities in coordinating extramural grants programs and stimulating new developments in the behavioral sciences as NIMH strengthens its research, training and service activities in the field of human behavior.

* * *

Homer L. Twigg, Jr., MD, of Bethesda, has been appointed chairman of the Department of Radiology in the Georgetown University School of Medicine.

Dr. Twigg was awarded his medical degree from the University of Maryland School of Medicine in 1951 and served his residency training in radiology at hospitals in New Orleans and Baltimore.

* * *

The new coronary care unit on Osler 6 of The Johns Hopkins Hospital started into service in November.

The special intensive care unit houses four beds and makes available a concentration of equipment and personnel for the best possible care of patients with acute myocardial infarction. In addition to the improvement in care of emergency coronary patients, the pilot unit will provide a valuable training experience for house staff, nursing staff and medical students.

Gottlieb Friesinger, MD, is medical director of the new unit. **Morrison Hodges, MD,** is assistant director.

* * *

Aris T. Allen, MD, Annapolis, has been selected to serve as minority Whip in the House of Delegates.

Elected by a 25-member Republican caucus at the opening of this year's session of the General Assembly, Dr. Allen is one of 11 negroes in the 185-member House.

* * *

David Rojas Morales, MD, of Baltimore, has been named a Diplomate of American Board of Obstetrics and Gynecology.

* * *

The newly formed Society for Adolescent Medicine, headquartered in Los Angeles, California, has added the name of **Louis J. Pratt, Jr., MD,** a Baltimore pediatrician, to its list of 200 charter members.

The Society has planned a two-day meeting in Washington the first week in March. The sponsors are Childrens Hospital of D.C. and Georgetown University School of Medicine.

* * *

The Committee on Basic and Clinical Research of the National Society for the Prevention of Blindness is accepting applications for grants for scientific study which will contribute to the basic understanding of eye function and pathology and improve methods of diagnosis, treatment and the prevention of blinding eye diseases.

Grants not exceeding $5,000 will be made for a one-year period for projects not being financed by other sources. Renewals may be applied for at the end of the year.

Deadline for applications is March 1, 1969. Application forms may be obtained by writing to the NSPB, 79 Madison Ave., New York, N.Y. 10016.

* * *

Maryland physicians recently named as Fellows-Elect to the American College of Obstetrics and Gynecology include: **Robert M. Barnett, MD,** Baltimore, and **John Edward Jeffrey, MD,** Beltsville.

Junior Fellows-Elect from the State are: **James Edward Anderson, MD,** Silver Spring; **Fritz Apollon, MD,** Baltimore; **George E. Engelke, MD,** Severna Park; **Pablito S. Luz, MD,** Rockville; **John J. Schruefer, MD,** Baltimore, and **Hong Chul Yoon, MD,** also of Baltimore.

* * *

Gerald Gelford, MD, has recently been appointed Radiologist at The Johns Hopkins Hospital and Instructor in Radiology, part time, at The Johns Hopkins University School of Medicine, Baltimore.

Editorial

The year 1966 stands as a memorable milestone with respect to Traffic Safety on the highways of Maryland. That was the year the Federal Highway Safety Act was passed; and the Medical and Chirurgical Faculty sponsored a state-wide Seminar on the Medical Aspects of Traffic Safety. At this meeting, J. Millard Tawes, then Governor of Maryland, commented,

> "As I have said so many times, highway safety is a joint responsibility of government and of citizens, acting either as individuals or collectively, as is the case with this group. Government should provide the leadership, but it cannot do the task alone."

The three principal gubernatorial candidates spoke at the luncheon meeting, the midpoint of the all-day seminar. None were willing to commit themselves to promotion of the so-called "Implied Consent" legislation, despite the compelling figures presented by the first speaker of the seminar.

TOO MUCH

Russell S. Fisher, MD, Chief Medical Examiner of Maryland, indicated that a total of 54%, more than half of all the drivers killed on highways in Maryland during 1965, had a blood-alcohol level in excess of .10%—at this figure it is presumed a person is intoxicated.

But other aspects of traffic safety were discussed that day as well. The drug-oriented society in which we live today was investigated in detail by John C. Krantz, PhD, former Professor of Pharmacology at the University of Maryland School of Medicine. He ably explained that the psychometric drugs—tranquilizers, alcohol—slow the reflex action time of an individual. He warned physicians that people should take and physicians should prescribe drugs that affect the central nervous system *only* when they are definitely indicated. And, more importantly, he strongly emphasized the necessity of warning the patient against the possibility of the drug adversely affecting the central nervous system, especially when operating a motor vehicle.

Abraham J. Mirkin, MD, of Cumberland, Chairman of the American Medical Association's Committee on Traffic Safety, also spoke at this session. His subject covered the medical conditions that could and do affect the driving ability of individuals. While the effect on drivers having such condition would vary with the individual, he stressed the importance of an evaluation being conducted by experts in the field involved. Maryland has a Medical Advisory Board to the Department of Motor Vehicles and evaluations are conducted when instances of physical conditions contributing to hazardous driving are evident. However, at best, it is a somewhat hit or miss program, post *ipso facto,* as compared to an evaluation that would take place *before* the incident or accident occurs.

TOO LATE

Not much has been done since 1966 to effect the changes recommended by this seminar. One accomplishment, however, has been an increase in the visual acuity requirements for drivers; a small item compared to the complete package of recommendations.

However, the 1969 General Assembly, now in session, will have under consideration a complete revision of the Motor Vehicle Code. Included in this revision will be ● the provision of implied consent, as well as provision for license revocation for persons convicted of offenses involving drunken driving; ● a suggestion that there be regular inspection of motor vehicles; ● a provision for driving under the influence of drugs . . . "an habitual user of . . . a drug to (such) a degree which renders him incapable of safely driving a motor vehicle"; and ● provision for driver re-examination on a regular basis.

In addition to the proposed revision of the entire Code, there will be, no doubt, individual bills designed to improve the traffic safety record in Maryland. A bill for the licensure of ambulances is under discussion, as are other provisions necessary for Maryland to receive Federal funds under the Federal Highway Safety Act.

All in all, this is an impressive package, but it is such because the State Legislature has failed in previous years to do what is necessary in the legislative field insofar as the Medical Aspects of Traffic Safety are concerned.

JOHN SARGEANT
Executive Secretary

Ten Commandments For Safer Driving

by Bill Johnston

I Thou shalt heed the stop sign.

The octagon tablet that calleth on thee to pause—and the lamp that turneth to red—hath real meaning to the wise; but they do make a temptation to the fool and the gambler. But to wager thy years against a moment truly giveth thee the appearance of an idiot who knoweth not the odds. The lamp of amber doth call upon thee for caution; and heedest thou it not, the charm of luck shalt depart from thee and thy days in traction shalt be long and miserable.

II Thou shalt not exceed the limits of speed.

Though the horses under thy foot be many, suffer them not to lead thee to thy destruction. Even though the Angel of Death rideth not on thy shoulder; the Eye of Radar doth spot thee from afar, and his master shalt carry thee before the judge.

III Thou shalt not pass when the way is not clear.

Thy life is surely thine own, if ye must cast it away, but thy wayfaring brother and the dependents that are his have no defense when thy juggernaut doth roar upon him in the left lane. They perish in the ruins; and thy ignorance shalt not wash from thy hand the blood of these innocent persons.

IV Thou shalt show courtesy unto others.

A journey unto the temple on a Sabbath hath small meaning if the screeching wheels of thy chariot doth make thy brethren cry out against thee. Thy blaring trumpet causeth not the objects in thy path to crumble; but verily, love doth depart from those who must leap unto safety, and they shalt call maledictions upon thy head.

V Thou shalt not follow too closely.

Tailgating shalt not only put knots upon thy brow; it surely turneth thy grille work into junk. It causeth thy insurance to zoom, and the Patrol to looketh upon thee with disfavor.

VI Thou shalt stay in thy proper lane.

The lanes that are marked for thy journey upon the highway are not for thy pleasure, but for thy safety. Weaving is the trade of the cloth maker; it is not that of the charioteer. It sendeth thy roadmates into ditch or pasture; and they loveth thee not. The blood of thy brother is precious unto him; spill it not with thy careless lane weaving.

VII Thou shalt dim thy lamps when needed.

The lamps of thy chariot are of many candles. Shouldeth thou blind the eyes of thy roadmates, they shalt charge thee with the fury of an herd of elephants; for though they have eyes, they seeth not. And verily, the bones of thee and thy adversary are hard for the gathering in the darkness.

VIII Thou shalt not drive unto exhaustion.

Thou shalt rest when thou are needful of it. Let not thy weary orbs deceive thee, nor pep pills be a prop unto thy tired brain; for they leadeth thee into eternity. And sleepeth thou at the wheel, thy earthly moments shalt be fewer than the mourners at thy tomb.

IX Thou shalt keep thy heap in good condition.

Thy chariot runneth not without attention. The counsel of him who careth for thy crate, if he be worthy, is good; for he is mindful of its needs. Thy life, mayhap, could be in the skilled hands that are his; and truly he hath the power to make thy journey carefree.

X Thou shalt not drive while partaking of drink.

The fruit of the vine may refresh thee after the completion of thy journey, but touch it not while wheeling unto thy destination. It maketh thee a man of distinction only to thine own self; and it aideth greatly in making a widow of thy helpmate. It shalt cause thee to lie in dark dungeons; and thine innocent victims shalt moan, and shalt die, upon the roadside.

Maryland Law

And The Drinking Driver

RUDIGER BREITENECKER, MD

Associate Pathologist, Greater Baltimore Medical Center
Associate Medical Examiner, State of Maryland

In 1968, 860 persons were killed on Maryland streets and highways. As in previous years, nearly 50% were drivers of which about half were under the influence of a significant amount of alcohol. No estimate of alcohol levels is available in drivers not killed in accidents because almost 50% refused to take the Breathalyzer test. Undoubtedly a large number of such motor vehicle operators were under the influence of alcohol, as evidenced by State Police Statistics:

> **Of 460 Breathalyzer tests given in 1968, 439, or 95%, had alcohol levels exceeding 0.10%. This is the level considered by the National Committee on Uniform Traffic Laws to be presumptive evidence that the driver is under the influence of alcohol.**

Maryland and several other states still adhere to the more liberal and more dangerous legal limit of 0.15% blood alcohol, while 14 states (Florida, Georgia, Illinois, Kansas, Maine, Michigan, Minnesota, New Mexico, North Carolina, North Dakota, Pennsylvania, Rhode Island, Vermont, Washington) have conformed to national and international recommendations by lowering the legal level to 0.10%. Utah has lowered its upper limit to 0.08% and New York has an 0.05% limit for drivers under 21.

In an effort to combat the escalating highway slaughter and to save many innocent victims by removing irresponsible drivers from the highways before they can kill or maim through their negligence, the following 30 states have passed an "Implied Consent Law": California, Colorado, Connecticut, Florida, Georgia, Hawaii, Idaho, Iowa, Kansas, Kentucky, Massachusetts, Michigan, Minnesota, Missouri, Nebraska, New Hampshire, New Jersey, New York, North Carolina, North Dakota, Oklahoma, Oregon, Pennsylvania, Rhode Island, South Dakota, Utah, Vermont, Virginia, Washington and West Virginia.

An "Implied Consent Law" provides that any person operating a motor vehicle shall be deemed to have given consent to a test to determine the presence and amount of alcohol in his blood if arrested for an offense involving the operation of a motor vehicle. In effect it gives the accused the choice of submitting to a breath or blood alcohol test or to a hearing before the Commissioner of Motor Vehicles to determine whether or not he should lose his license. The scope of such a hearing will cover the issues of whether an arresting officer had reasonable grounds to believe the driver had been under the influence of alcohol, whether he was legally arrested and advised of the penalties for refusing to take the test and whether he refused to submit to the test requested. It does not abrogate the individual's right for his day in court, where the question of whether the driver actually operated under the influence of alcohol would be decided after consideration of all the circumstances and available evidence. The states with this law have accepted the rulings of many different courts including the U.S. Supreme Court that a law of this nature does not violate any of the constitutional guarantees.

The effectiveness of such laws in curbing traffic accidents has been demonstrated in various states and in European countries, such as Austria and Great Britain, which have adopted 0.08% as the legal limit.

Since the introduction of the Breathalyzer test in 1967, late night traffic accidents in London have fallen 41%, deaths by 33% and serious injuries by 22%, when compared to the same period before the advent of breath alcohol testing.

It is generally recognized that the chance of being involved in an accident with a blood alcohol level of 0.05% to 0.10% is 150% higher than when sober. From 0.10% to 0.15% the risk is 250% greater and above 0.15% the chance is 1,000% better. The main reasons are that any drinking of liquor increases reaction time, impairs visual and perceptive ability, decreases comprehension and affects the psychological phenomena of risk-taking, attitude and judgment.

The fact that under the present laws in Maryland the test can be refused without penalty lessens the certainty of detection and consequently lessens the deterrent value of the alcohol test program. Since driving skill cannot be measured conveniently under ordinary circumstances, the measurement of the alcohol level is the only objective criterion for determining whether a driver's ability has been sufficiently impaired to be unsafe. Without such physical evidence courts are seriously hampered in administering justice in a large percentage of "drunk driving" cases.

For these reasons the Medical and Chirurgical Faculty supports an "Implied Consent Law" and the lowering of the blood alcohol limit to 0.10% following recommendations of the American Medical Association, the National Safety Council and other organizations including the American Trial Lawyers Association and following the lead of the numerous states listed above.

Confusion often exists as to the necessary curtailment of social drinking in order to stay below an 0.10% blood alcohol level. The limitation is not as great as one might imagine. For example, an average person must drink at least 3 to 4 ounces of liquor or 3 to 4 bottles of beer in one hour to reach a 0.10% alcohol level. To reach a blood alcohol percentage of 0.15% he must have consumed about 6 one-ounce drinks of 100 proof liquor in one hour. This would be heavy drinking for the average social drinker. The consumption necessary to reach these levels increases with body weight and with the span of drinking time.

In addition to the promotion of highway safety, physicians also are interested in another less commonly recognized benefit of alcohol testing. Such a test may be essential to distinguish symptoms due to injury or illness from those due to alcohol intoxication. If the symptoms commonly associated with alcoholic influence are observed, a negative breath or blood test would suggest a medical emergency. In these instances prompt medical attention rather than incarceration is essential and may be a life-saving measure.

The problem of the driver under the influence of alcohol demands vigorous action. The enactment of an "Implied Consent Law" and the lowering of the legal alcohol limit would provide a significant improvement in traffic safety and would put Maryland on a par with the progressive states and nations. Such measures deserve the wholehearted support of all citizens concerned with traffic safety. Physicians can help the passage of these bills, which again will be introduced in the next legislative session, by expressing their support to their state senators and delegates.

"Implied" Consent—

Of all the thousands of legal cases pending in the state, approximately 85% are concerned with motor vehicle accidents, and the damages and injuries that have occurred as a result of them.

The following article is an excerpt from a presentation on the Legal Problems Involved in the Development of Legislation by J. Dudley Digges, Chief Judge, Seventh Judicial Circuit, State of Maryland, presented October 12, 1966 at the Seminar on the Medical Aspects of Traffic Safety, sponsored by the Faculty and the Maryland Chapter of the American College of Surgeons.

Judge Digges proposes that legislation, in whatever form, should relieve the courts of trying many of the motor vehicle cases, and place the responsibility for the mishandling of a motor vehicle on the driver himself, with the medical profession and the Commissioner of the Department of Motor Vehicles setting the necessary standards for reinforcing this sense of responsibility.

And What It Implies

"It is important that we do everything both in and out of the medical field, both in and out of the legal field, and indeed both in and out of all fields, to attempt to solve this problem, which is becoming such a menace all over America that it would not surprise me if someone suggested the only answer to it was to outlaw the automobile itself." These were the sentiments presented by J. Dudley Digges, Chief Judge (Seventh Judicial Circuit) during the Seminar on the Medical Aspects of Traffic Safety.

To date, the automobile has not been outlawed—we doubt if it ever will be—and we are no closer to a solution than we were three years ago, the main problem being that whatever solution is attempted must fall within the framework of constitutional privileges. This framework, in turn, is dependent upon certain developments, in this case, a certain "unanimity among physicians" to the point where a law can be based on sound principles.

According to Judge Digges:

The number one requirement here is that the statistics you gather, which show, for example, that a certain percentage of alcohol in the blood destroys the effectiveness of a driver, be a reasonable basis for a decision. This can be determined only by you in the medical field and by those associated with you.

From a legal point of view the problem goes back to the concept that the driving of a motor vehicle is a privilege and not a right.* Just how long that concept will continue in effect I do not know, but when it changes, and it is determined that driving is a right rather than a privilege, then all of the decisions of the law that have been made or suggested will go down the drain along with the present concept.

A change may come as we in this country become more and more dependent upon the automobile for our livelihoods. . . . It may be that one of these days it can be so wound up in our daily lives that the operation of a motor vehicle will be deemed a right, guaranteed by the various provisions of the constitution, and not a privilege.

* The concept of driving a car as a privilege was adopted by the National Conference of Commissioners on Uniform State Laws in 1957, and approved by the American Bar Association in the same year.

Meanwhile, in today's law we deal with this as a privilege, a privilege which is granted to an individual, but which may be withdrawn, provided of course that the reason for withdrawal meets other constitutional tests, and provided that all in the same category are treated alike.

It is within this framework that some of the proposed laws are referred to as the "implied consent" laws.

The law provides that anyone who applies for an operator's permit and who uses that permit to operate on the highways of the state, impliedly consents to a test to determine whether or not he was driving under the influence of alcohol and to the withdrawing of blood, providing it is done by a doctor, a qualified technician, chemist, registered nurse or someone in an allied field.

The law then specifies—and this must be based on medical conclusion, with reasonable unanimity among your profession—what degree of alcohol, in what category. Of course the law would have to be changed if you made discoveries which changed your conclusions.

There are many other laws that could be considered. For example, there could be a law based not on *implied* consent, but on *affirmed* (express) consent and requiring the individual to sign the consent in order to get a license. That has its drawbacks, however, because out-of-state drivers in a state with such a law may not be subject to it in their home states and implied consent would be applicable to them.

One case that seems to have a great bearing on this problem was one decided in June, 1966.

The case was one that arose in California (Schmerber vs State of California). The defendant was initially convicted in the Los Angeles Municipal Court for driving a motor vehicle while under the influence of intoxicating liquor. After the defendant's arrest, while he was in a hospital receiving treatment for the injuries suffered in the automobile accident, a blood sample was withdrawn by a physician at the direction of the police officer, acting without a search warrant, despite the defendant's refusal on the advice of his counsel, who was present, to consent to the blood test.

The report of the chemical analysis of the test, indicating intoxication, was admitted in evidence at the trial over the defendant's objection that the compulsory blood test, and the admission of the evidence thereof, violated his right to due process of law under the Fourteenth Amendment, and his privilege against self-incrimination under the Fifth Amendment, his right to counsel under the Sixth Amendment, and his right against unreasonable searches and seizures under the Fourth Amendment, insofar as such rights were secured against the states by the Fourteenth Amendment. So the whole gamut of constitutional objections was raised in this case.

Amazingly enough, the Supreme Court *upheld* the decisions of the California courts five to four. I say "amazingly enough" because the tendency had been five to four the other way up until this case.

The justices decided that the defendant was not deprived of due process of law because the withdrawal was made by a physician in a simple, *medically acceptable* manner in a hospital environment.

The contention, under the Fifth Amendment which guarantees any defendant the privilege against self-incrimination, that this defendant in "submitting" to the taking of his blood was required to give evidence against himself (which, of course, was made unlawful long ago when the Magna Carta was extracted from King John of England) was denied by the Court:

"It could not be denied that in requiring petitioner to submit to the withdrawal and chemical analysis of his blood, the state compelled him to submit to an attempt to discover evidence that might be used to prosecute him for a criminal offense. He submitted only after the police officer rejected his objection and directed the physician to proceed.

"The officer's direction to the physician to administer the test over petitioner's objection constituted compulsion for the purposes of privilege. The critical question, then, is whether petitioner was thus compelled 'to be a witness against himself'.

"History and a long line of authorities in lower courts have consistently limited its protection to situations in which the state seeks to submerge those values for obtaining the evidence against an accused through 'the cruel, simple expedient of compelling it from his own mouth'." Implicit, no doubt, was that this would apply to all things. The Court laid stress on the fact that the drawing

of a little blood was of a very minor nature and akin to compelling a man to submit to a fingerprint test.

"In the present case, however, no such problem of application is presented. Not even a shadow of testimonial compulsion upon, or enforced communication by, the accused was involved either in the extraction or in the chemical analysis. Petitioner's testimonial capacities were in no way implicated; indeed, his participation, except as a donor, was irrelevant to the results of the test, which depend on chemical analysis and on that alone."

The question of whether or not the defendant was denied right to counsel was answered by the Court in saying you cannot argue that he was deprived of counsel just because counsel was not permitted to have him do what he wanted to do and if a lawyer advised him not to submit to the test, he was erroneously advised.

As for the search and seizure problem: "The interests in human dignity and privacy which the Fourth Amendment protects forbid any such intrusions on the mere chance that desired evidence might be obtained. In the absence of a clear indication that in fact such evidence will be found, these fundamental human interests require lay officers to suffer the risk that such evidence may disappear unless there is an immediate search."

But, when there is probable cause to believe that the person may be guilty of the violation of this law, that in itself was justification for the officer requesting the examination over objection, and that if there exists probable cause—smelling of alcohol on the breath, the way the vehicle was being operated, the result of the accident itself—those things in themselves can be taken into account; that if there was probable cause to believe he had too much to drink, that was justification for the arrest, and when there is an arrest, anything that may be found on him and used in this respect is admissible.

It is not merely a question then of dealing with a driver's license. Even in a criminal case (which this was) where the man's liberty might depend upon the result, these constitutional guarantees do not prohibit the taking of blood as it was taken in this case. And, as far as I know, it is the generally accepted way and not peculiar to the case in question.

But it is a serious problem. I am not suggesting that we do not need further legislation. I am suggesting that maybe the time has come to utilize all facilities. The reason is simply this: Fundamental in the American Constitution is the right to trial by a jury. Maybe you would and maybe you would not be amazed at the reluctance of juries to convict people of driving under the influence of liquor.

I admit times have changed, but I remember the first year I was out of law school. I tried before one jury 15 driving-under-the-influence-of-liquor cases and was successful in having 15 of them found not guilty. This was no great feat on my part; juries would not convict anyone. They are reluctant it do it today, because they figure there is a great possibility that "I could be sitting in that defendant's chair."

Therefore I think it is important that we deal with the criminal problem and that we also go one step further and consider the desirability of abolishing most motor vehicle laws as being violations of the criminal laws.

I admit that sounds rather drastic, but let me explain. Among my duties, I sit in juvenile court, and I have young people before me who are charged with all kinds of things—not necessarily motor vehicle charges. I can tell a boy I am going to send him to training school for six months and get no reaction, but as soon as I tell him I will take his driver's license, and give it to the State's Attorney to be returned to the Commissioner of Motor Vehicles, an 18-year-old boy will start to cry.

So I think the way to deal with this problem is to withdraw the individual's privileges when the law has been abused. There should be a simple process to determine that *without* submitting a case to a jury or anyone else.

I realize there have to be certain fundamental safeguards, but we have them now in various boards. The Commissioner of Motor Vehicles passes on the question of whether or not the license is to be withdrawn after a conviction. I do not think it is necessary to impose conviction in the first place. If a motor vehicle operator abuses his privilege for which he is licensed, then his privilege should be withdrawn until he demonstrates a sense of responsibility.

Your Patient's Life—
How Can You Protect It?

S. BAKER
T. BAKER
The Johns Hopkins School of Public Health
Department of Public Health Administration

If your patient is a young adult, in his most productive years, he is more likely to die from an accident than any other cause. If the current trend continues, we can expect about *900 traffic deaths* in Maryland this year. There are two important ways in which you, as a physician, can keep your patients from being numbered among them.

First, advise all of your patients not to drive after having more than two drinks. More than half of all traffic deaths are associated with alcohol.[1, 2] If your patient is an alcoholic, or has a drinking problem, he is especially likely to cause death or injury to himself or others. No other single factor approaches alcohol in importance as a cause of accidents.

Second, urge each of your patients to wear seat belts or diagonal safety straps at all times. The combined three-point belt has been shown to prevent fatal injuries from occurring at speeds of less than 60 miles per hour—whereas unrestrained persons are killed at speeds as low as 12 miles per hour.[3] Seat belts alone are believed to prevent most fatalities and greatly reduce the extent of injuries.

Nationally, the number of motor vehicle fatalities increased by about 40% between 1959 and 1967. As a physician, you are in a strong position to combat this trend, by counseling your patients to take these life-saving precautions.

The following papers, pages 57-64, were prepared by the Maryland Heart Association for this Journal.

Present Status of Permanent Pacing of the Heart

After almost a decade of experience, the safety and effectiveness of implanted permanent pacemakers has become apparent. Although certain attitudes and methods continue to change, most of the principles of the use of pacemakers are well established.

VICTOR PARSONNET, MD
Director of Surgery
Beth Israel Hospital, Newark, New Jersey
Clinical Associate, Professor of Surgery
New Jersey College of Medicine and Dentistry

Indications

At first, the only indication for insertion of a permanent pacemaker was complete heart block with Stokes-Adams seizures. Today other arrhythmias (Table I) are also treated with permanent implants, because a reliable implantable standby (demand) pacemaker has been developed. This has extended the use of pacers to those conditions where competition between the pacemaker and naturally occurring beats is likely to occur.

TABLE I
Indications for Permanent Pacemaker Implantation

1. Complete atrio-ventricular heart block especially with Stokes-Adams episodes
2. Symptomatic bradycardias
   - Atrial fibrillation with high degree atrio-ventricular block
   - Sinus arrest
   - Digitalis induced bradycardia
   - Intermittent high degree atrio-ventricular heart block
3. Persistent tachycarrhythmias
4. Left axis deviation and right bundle branch block suggestive of bilateral bundle branch block (possible indication)

Patients may survive many years with complete heart block with medical therapy alone, but most of them die suddenly within two to four years, presumably of a Stokes-Adams attack. Moreover, most patients with chronic complete atrio-ventricular heart block, who were "asymptomatic" before pacing, notice improvement in their sense of well-being after pacer implantation, presumably because of enhanced systemic blood flow. Therefore, as a rule, most patients with complete heart block should be paced, whether they have Stokes-Adams or not.

Method

There are two approaches in implanting a pacemaker: transthoracic (or transdiaphragmatic) and transvenous. In one, the electrodes are sewn directly onto the heart muscle, and in the other they are placed in the heart via a suitable vein. We now use the transvenous method exclusively because the operation can be accomplished under local anesthesia and therefore may be performed even in bad risk and aged patients with but minor complications and morbidity, and less than 1% mortality, (Table II).

TABLE II
Mortality Following Pacemaker Implantation

	Complete Operations	Number of Patients	Number of Operative Deaths
Transthoracic (including transdiaphragmatic)	85	74*	2 (2.5%)
Transvenous	199	174**	2 (1.0%)
Totals	284	248***	4 (1.5%)

* Including 1 converted from transvenous and 4 converted from transthoracic to transdiaphragmatic.
** Including 15 converted from transthoracic.
*** 20 patients counted twice.

The pacer implant is done by a team, consisting of a cardiologist trained in heart catheterization, a surgeon, and an electronics technician. Under local anesthesia an electrode catheter is inserted through either cephalic or external jugular veins, and positioned in the apex of the right

ventricle. The threshold for stimulation (excitation threshold) is measured with an external battery powered pulse generator to confirm the satisfactory position of the electrode. (An excitation threshold above 0.9 to 1.0 milliamperes is unacceptable.) The catheter electrode is fixed in place in the vein and the power pack is implanted in a subcutaneous pocket in the upper chest wall. The patient is ambulatory in a day or two and ready for discharge within a week.

Complications with this method occur in 10% of cases. Included in this figure are component and battery failures. Other complications can be avoided or reduced by proper attention to implantation techniques. For example, broken leads can be prevented by proper handling of the electrodes and by placing the pulse generator in the pectoral position where there is little flexing of the wires. Electrode dislodgement can be prevented by fixing the electrode well into the vein, and by positioning it at the very apex of the right ventricle.

A rise in excitation threshold above the output of the pacemaker (exit block) occurs if the electrode becomes separated from the myocardium by scar tissue as a result of poor initial placement, secondary infection, or perforation of the heart. Careful attention to details has almost eliminated these problems.

Preliminary Transvenous Pacing

Although it is tempting to insert a permanent pacemaker as a primary operation, preliminary transvenous pacing is the rule at this institution. A temporary bipolar electrode is inserted through a suitable vein (external jugular, antecubital, femoral or saphenous) into the outflow tract or the apex of the right ventricle. Immediate control of ventricular rate is thereby achieved. Definitive implantation can therefore be done electively, and anesthesia, if needed, can be employed with safety.

Pacing Mode

Three modes of pacemakers are available: fixed rate, P-wave synchronous, and standby. The fixed rate pacer fires at a constant rate which may in some models be altered by external manipulation. The P-wave synchronous pacer rate is determined by the sinus node rate. It is commercially available only for implantation by thoracotomy, not pervenously. The standby or demand pacer fires when the spontaneous rate falls below a preset level. Fixed rate pacing has the advantage of being well tested by time. It is reliable and likely to last three or more years, and therefore is still the method of choice in many clinics.

There is evidence, however, that fixed rate pacing may be dangerous in those patients who have "competition" between spontaneous and paced cardiac complexes. Fatal ventricular fibrillation can occur from stimulation of the heart by the pacemaker when the stimulus falls at the apex of the preceding T-wave. Although at most times the paced human heart may be relatively insensitive to competition, the fibrillation threshold may be lowered by anoxia, digitalis, or electrolyte imbalance. In such situations, competition can produce repetitive rhythms and ventricular fibrillation.

There are now numerous reports of unexplained sudden deaths in paced patients. Eleven sudden deaths have occurred in our series of 228 patients; ten of these patients were paced with fixed rate pacemakers in the presence of competition.

The standby pacemaker fixes effective stimuli only when the spontaneous heart rate falls below preset limits. It thus avoids the dangers of competition and is displacing the fixed rate pacer in many institutions.

Follow Up

Experience with a follow-up clinic has shown that the best way to determine when to change the pacemaker is to analyze the expanded electric impulse (artifact) of the pacemaker. Changes in the pulse rate, and the height, duration, and contour of the artifact, may indicate that pacemaker failure is impending. Seventy-five percent of changes in our clinic have been elective as a result of such an analysis. The use of a computer facilitates this type of study.

Future

Batteries in existing pacemakers last from two to four years, depending upon the model. The longest life of any pacemaker in our series was 47 months. The electrodes and wire leads, on the other hand, last much longer. Therefore, the most important advance in the future will be an improved power source. This may be in the form of a radioisotope generator now under development. There have also been changes in electrode design that may significantly reduce power requirements and thus increase battery life.

Emergency Treatment of Acute Pulmonary Edema

PHILIP SAMET, MD
Section of Cardiology
Department of Internal Medicine
Mount Sinai Hospital of Greater Miami
Miami Beach, Florida

Acute pulmonary edema is a common, dramatic and often catastrophic event in the life history of the cardiac patient. It is primarily an expression of disease of the left side of the heart and is therefore seen in patients with acute myocardial infarction, mitral valve disease especially mitral stenosis, aortic stenosis, aortic regurgitation, severe hypertension, and occasionally in individuals with rapid tachycardias or pulmonary embolism. Rarer types of pulmonary edema include high altitude pulmonary edema, pulmonary edema following drowning or exposure to noxious gases, and that associated with acute renal insufficiency with overhydration. On rare occasions, pulmonary edema has been associated with neurological disease including trauma and intracerebral hemorrhage.

In the previously untreated patient the cornerstones of treatment of acute pulmonary edema are:

1) sedation, usually with morphine
2) improvement of myocardial function by digitalization
3) onset of rapid diuresis with the newer diuretic agents
4) decreasing venous return and right ventricular output
5) removal of precipitating and aggravating factors such as tachy-arrhythmias, paroxysmal hypertension, arterial hypoxemia, metabolic or respiratory acidosis, and increased work of breathing.
6) proper positioning of the patient.

The above therapeutic measures are most often used concurrently rather than consecutively, especially if the pulmonary edema is severe. Formerly, discussion often centered about the concept whether morphine or digitalis was the most important form of therapy in acute pulmonary edema. The development of the newer diuretic agents such as ethacrynic acid and furosemide has added another primary form of treatment for this condition. Generally, all three agents are administered early in the course of therapy for severe pulmonary edema, in addition to placing the patient in the upright position unless shock is present.

Morphine is best injected intravenously over a two to three minute interval in a dose of 8-10 mg. If necessary an additional 5-10 mg may be given one-half hour later. In mild cases the drug may be given subcutaneously or intramuscularly. Morphine therapy alone will often terminate the mild case of pulmonary edema. If respiratory depression results from morphine administration, nalorphine hydrochlorid (Nalline) should be given intravenously in 5 mg doses which may be repeated once or twice at 20-30 minute intervals. Morphine should be avoided in patients with a history of allergic asthma or chronic pulmonary disease, especially if the arterial carbon dioxide tension (pCO_2) exceeds 45-48 mm Hg. Pulmonary edema in patients with cerebrovascular trauma or accidents should also be treated without morphine. Morphine therapy may result in varying degrees of hypotension which may in turn require therapy.

Improvement of myocardial contractility by digitalis is a second foundation of therapy. Intravenous therapy is generally advisable. If the situation is extremely grave and if the physician is

experienced in the use of ouabain, 0.5 mg of this glycoside is given by vein and followed by further doses of 0.1 mg every half hour to a maximum of 0.8-1.0 mg or until clinical improvement is noted. One must be certain that the patient has *not* been receiving digitalis therapy for at least two and preferably three weeks if intravenous digitalis preparations are employed. Much more frequently lanatoside C or digoxin are utilized for rapid intravenous digitalization of patients in pulmonary edema. The time of onset of action of these latter two agents is less than one hour when given intravenously. If digoxin is utilized, 1.0 mg is given intravenously, followed by one or two 0.25 mg doses if needed. Maintenance therapy with oral or intramuscular digoxin may then be employed.

The development of rapidly acting diuretic agents—ethacrynic acid and furosemide—has altered the therapy of acute pulmonary edema. The use of 1-2 ml of a mercurial diuretic intravenously was formerly advocated, but since the onset of a diuresis was delayed for four to six hours, the issue was usually decided before an effective diuresis ensued. However, administration of either ethacrynic acid or furosemide results in much more rapid diuresis. Both agents when given intravenously produce the onset of diuresis within 15-20 minutes. A liter of urine will often be produced within 60-90 minutes. Oral administration produces onset of diuresis within 60-90 minutes. Ethacrynic acid is given in doses of 50-100 mg intravenously in pulmonary edema. Oral therapy (100 mg) is less desirable for therapy of pulmonary edema. Furosemide has not as yet been released for intravenous administration but is available for oral use. Theophylline derivatives such as aminophylline (0.24-0.48 G in 20 ml of solution and given slowly intravenously) are advocated by some clinicians, but this observer has seen little evidence of a beneficial effect unless severe bronchospasm complicates the picture of pulmonary edema. Similarly, surface tension reducing agents such as ethyl alcohol have not been of significant benefit in our hands.

Measures to decrease venous return are employed, especially when the above approaches are not effective or only partially effective. The primary measures in this category include rotating tourniquets and phlebotomy. Phlebotomy is accomplished by removal of 500 ml of blood as rapidly as possible. Positive pressure breathing may also be employed to decrease venous return. Blood pressure must be watched carefully during positive pressure breathing to prevent serious hypotension. Other measures to decrease venous return, such as spinal anesthesia and stellate ganglion blockade, have been suggested to decrease venous return, but have been limited use. Ganglionic blocking and sympatholytic agents such as mecamylamine (1-3 mg diluted in 50 ml of 5% glucose in water and given slowly intravenously), hexamethonium, dibenamine, and dihydroergokryptine have been employed but experience has been limited. The one situation in which these agents may be useful is in the treatment of pulmonary edema in patients with severe systemic hypertension.

The last category of therapeutic measures embodies the removal of precipitating factors. These include the correction of arrhythmias with rapid or slow ventricular rates. Arterial blood gas analysis has become an essential aspect of therapy in patients in pulmonary edema who do not readily respond to treatment. The most common acid-base abnormality detected is respiratory alkalosis which does not require specific therapy. Decreased peripheral perfusion due to low cardiac output is often a cause of metabolic acidosis, which requires correction with intravenous sodium bicarbonate. Occasionally, endotracheal intubation or tracheostomy are required for adequate carbon dioxide exchange. Correction of arterial hypoxemia is accomplished by inhalation of high oxygen mixtures and correction of the pulmonary edema. The role of hyperbaric chambers in correction of arterial oxygen unsaturation remains for future study. Surgical correction of aortic and mitral valve disease may be needed to prevent recurrent pulmonary edema. The final precipitating factors of pulmonary edema that may readily be dealt with involve restriction of activity and prevention of excessive sodium intake.

Utilization of one of the varied types of assisted circulation such as veno-arterial shunting, left heart bypass of counterpulsation offers future promise for the therapy of patients with non-responsive pulmonary edema, but the clinical value and role of these methods have not yet been determined. On the other hand, peritoneal dialysis with hypertonic glucose solution offers a more immediately available palliative procedure for a few selected patients with non-responsive continual pulmonary edema.

Clinical Applications of Inhibition of Beta-Adrenergic Receptors with Propranolol

Propranolol, the first clinically useful beta-adrenergic blocking drug, was recently placed on the market after several years of exhaustive clinical trials. On the basis of many investigations, it appears that blockade of the beta-adrenergic receptors may be useful in the treatment of several types of cardiac problems. However, as with any potent drug, the physician must possess full knowledge of its mechanism of action and possible hazards before prescribing. This article is intended as a brief survey of the actions and uses of propranolol for the practicing physician.

MORRIS STAMPFER, MD

Acting Chief, Cardiology Branch,
Chief, Section on Circulatory Physiology
Cardiology Branch, National Heart Institute
Bethesda, Maryland

Pharmacology

The work of Dale, Ahlquist and others has established the existence of different types of responses to adrenergic stimulation, dependent on the presence of either of two types of receptor sites in the tissues. For example, stimulation of alpha-adrenergic receptors causes constriction of blood vessels, while stimulation of beta receptors causes vasodilation. Only beta receptors are located in the heart, and stimulation of these receptors results in an increase in the heart rate and the force of cardiac contraction. The endogenous catecholamines, epinephrine and norepinephrine, stimulate both alpha and beta receptors, while the catecholamine isoproterenol stimulates beta-adrenergic receptor sites exclusively. Although alpha-adrenergic blocking drugs have been known for many years, propranolol is the first generally available drug which antagonizes the action of catecholamines at the beta-adrenergic receptor sites, thus causing slowing of the heart rate and a decrease in the force of cardiac contraction.

Clinical Uses

1. *Angina Pectoris*

Angina pectoris is due to a disproportion between the O_2 requirements of the myocardium and the O_2 supply so that the supply of oxygen is inadequate to meet myocardial metabolic demands. In theory, angina can be relieved either by increasing oxygen delivery or decreasng metabolic requirements. Since both heart rate and the force of contraction are important in determining the amount of O_2 required by the heart, propranolol, by decreasing these parameters during exercise, is often successful in relieving angina that is refractory to the more commonly used drugs. The dose required is highly variable and is best ascertained by starting with a small dose such as 10 or 20 mg by mouth four times daily, and increasing gradually until attacks of angina are substantially reduced in frequency. Doses of 400 mg daily or more have occasionally been used, although the most commonly required dosage ranges from 120 to 240 mg daily. Very close observation of the patient is necessary since congestive failure may appear. Such symptoms may often be controlled with digitalis glycosides and diuretic agents. However, if these interventions are not successful in controlling symptoms of failure, propranolol must be discontinued.

2. *Arrhythmias*

Propranolol can be used in the treatment of various cardiac arrhythmias; its beneficial effects are due not only to beta-adrenergic blockade, but in certain arrhythmias to a quinidine-like action as well.

Propranolol may abolish arrhythmias caused by digitalis intoxication, including frequent premature ventricular contractions and ventricular tachycardia. It should be stressed, however, that there is no evidence that propranolol is superior to some of the other commonly used antiarrhythmic agents.

In arrhythmias not due to digitalis, such as atrial fibrillation or atrial flutter with rapid ventricular response, propranolol usually can be relied upon to slow the ventricular rate. Recurrent attacks of paroxysmal atrial tachycardia may occasionally be reduced in frequency or prevented by propranolol, although sufficient information to assess long-term results is not yet available.

When emergency treatment is required, propranolol should be given intravenously in doses of not more than 0.5 mg every three to four minutes until the desired effect is achieved or signs or symptoms of worsening cardiac decompensation are noted. The drug should not be used in complete atrioventricular block with idioventricular rhythm (unless a cardiac pacemaker is in place) since electrical activity may be slowed further or arrested.

3. *Idiopathic Hypertrophic Subaortic Stenosis*

Propranolol has been found to be beneficial in many patients with idiopathic hypertrophic subaortic stenosis (IHSS). The exercise tolerance of patients, whose primary symptom is angina pectoris, has been improved by propranolol, and the frequency of syncopal episodes and of arrhythmias can be reduced in other patients. The reason for this improvement probably is due to the fact that obstruction to left ventricular outflow in IHSS is made worse by drugs or maneuvers that increase the contractile state of the heart, such as isoproterenol or exercise. Propranolol, by decreasing sympathetic stimulation of the heart, decreases this obstruction. This change is less marked at rest, when there is normally little sympathetic stimulation present, but becomes more significant during exercise.

It should be stressed that in patients with IHSS and congestive failure, the drug may produce deleterious effects just as in patients with other types of heart disease who have signs and symptoms of cardiac failure.

Side Effects and Contraindications

By interfering with sympathetic stimulation to the heart, propranolol decreases the cardiac output response to exercise in normal subjects, and thereby impairs their capacity to perform intense exercise. This finding demonstrates the significant role of the sympathetic system in the cardiac response to the stress of exercise. Propranolol also alters the diurnal pattern of sodium excretion in normal subjects and in patients with mildly impaired cardiac function. However, in patients with severe cardiac decompensation its administration may cause frank retention of sodium and fluid, changes resulting in progressive edema accumulation and symptomatic deterioration. Thus, in patients with heart disease whose cardiac reserve is diminished and who depend upon sympathetic support to maintain compensation, inhibition of cardiac sympathetic stimulation may lead to severe and sometimes irreversible symptoms of cardiac failure.

Other major side effects that have been reported are severe hypoglycemic reactions occurring in patients taking insulin or oral hyperglycemic agents, and acute pulmonary insufficiency due to bronchospasm, a complication that may occur in patients with obstructive airway disease.

Summary

Blockade of the beta-adrenergic receptors is of significant benefit in selected patients with various types of heart disease. Angina pectoris, digitalis-induced arrhythmias, atrial fibrillation and flutter, and idiopathic hypertrophic subaortic stenosis are conditions in which this drug may be useful. However, caution and continued close observation of the patient is always necessary because removal of sympathetic support to the failing heart may result in severe cardiac decompensation. Propranolol and other beta-adrenergic blocking drugs should not be administered to patients with congestive heart failure that does not respond to digitalis glycosides and diuretics, and to patients with atrioventricular block, unless a cardiac pacemaker is in place. In addition, they should be given with extreme caution to patients with obstructive airway disease and to patients taking insulin or oral hypoglycemic agents.

In the evaluation of a patient with valvular or coronary artery disease, the history and physical findings may disclose that a significant functional impairment is present. It is not generally possible from the clinical examination to adequately separate that limitation due to mechanical factors (such as valvular disease) from that due to a concomitant abnormality of the myocardium. The rheumatic process itself, and/or changes secondary to a valvular lesion, may result in such significant changes in the myocardium that the status of the heart muscle becomes the most important factor relative to the patient's operative risk and subsequent morbidity. Myocardial function may also be adversely affected by coronary artery disease increasing the functional limitation in patients with valvular disease. This is of additional importance now that surgical measures for the relief of isolated arteriosclerotic heart disease are available.

The Evaluation of Left Ventricular Myocardial Function in Patients Undergoing Cardiac Surgery

JOSEPH W. LINHART, MD
Chief, Cardiac Catheterization Laboratory
Mount Sinai Hospital of Greater Miami
Miami Beach, Florida

In order to gain information regarding the myocardial status in a given patient, various physiologic and angiographic procedures are performed in exercise and cardiac catheterization laboratories. The presently clinically applicable examinations include: 1) *Measurement of left ventricular end-diastolic pressure (LVEDP) and cardiac index (CI).*

Although a high LVEDP was once considered to indicate left ventricular failure, we now know that the LVEDP may be elevated due to a pressure load (aortic stenosis) or volume load (aortic or mitral regurgitation), and no evidence of left ventricular failure or poor left ventricular function may be present. Similarly, a reduction in CI does not necessarily indicate poor myocardial function in patients with valvular disease. An elevated end-diastolic pressure in patients with coronary artery disease has more significance however, as our studies have invariably demonstrated a decrease in left ventricular function in these patients.

Since measurement of resting intracardiac pressure and cardiac index may provide incomplete

data in some cases, the patient's response to: 2) *Muscular exercise* can be determined.

The relationship between LVEDP, cardiac output, stroke work and volume, and oxygen consumption is determined at rest and during exercise, usually in the supine position on a bicycle-type ergometer. Normally, the cardiac output will increase by more than 500 cc per minute for each 100 cc increase in minute oxygen consumption. Also, the LVEDP will fall or increase by no more than 2 to 3 mmHg while the stroke work and stroke volume rise. A failing or abnormal left ventricle will have a significant rise in LVEDP (more than 3 mmHg), associated with little increase in stroke work and a falling stroke volume.

A common method used in our laboratory to stress the LV is through: 3) *Angiotensin infusion.*

In this test, angiotensin is infused, I.V., in doses of 2 to 4 micrograms per minute to produce increases in arterial pressure (afterload) in systolic increments of 25 to 30 mmHg. The normal LV responds to this stress by large increases in stroke work with only small increases in LVEDP. A poorly functioning LV increases its end-diastolic pressure (EDP) markedly, but the stroke work rises slightly or even decreases. This test has proven to be especially valuable in patients with coronary artery disease where it may provide the only indication of decreased LV function.

Muscle function may also be evaluated, qualitatively by: 4) *Angiography.*

The injection of contrast material into the LV is filmed on 16 or 35 mm film and then evaluated in various ways for chamber size and shape, sequence, uniformity, and magnitude of contractions and for associated abnormalities such as mitral valve insufficiency or ventricular aneurysm. Abnormalities in the contraction pattern indicate a disorder of left ventricular function. We have found an excellent correlation between LV function demonstrated in this manner and the angiotensin stress test when the LV cineangiogram denotes abnormal function. The LV cineangiogram may be entirely normal, however, and an abnormality of function may only be demonstrated by some form of LV stress testing.

It is also important to determine the angiographic integrity of the coronary arteries in the preoperative evaluation of a patient with valvular heart disease. Although a patient with severe coronary artery disease may have normal LV function, more often there is a functional impairment which affects the immediate surgical risk and subsequent long-term results. This is over and above the risk inherent in the valvular surgery itself.

It must be mentioned that although these four routinely used methods are valuable for the determination of left ventricular function, they are only indirect estimates. It is more appropriate to relate the tension or force developed in a muscle to the extent and velocity of muscle shortening. This is only done experimentally, today, and necessitates numerous assumptions in patients. Eventually, however, it will be possible to extend these techniques to routine clinical practice.

Clinical experience has now shown that in otherwise comparable patients those with poor myocardial function have the highest operative risk, stormiest post-operative course, and the poorest post-operative function. Several factors may be important to explain post-operative morbidity to patients undergoing valvular replacement. 1) Significant leakage around the rim of the prosthetic valve. 2) Other residual valve lesions. 3) Prosthetic valve gradients. 4) Coronary artery disease. 5) Poor myocardial function. It is necessary to determine, using the previously mentioned diagnostic tests, which of these factors is important since the first three, and occasionally the fourth, are open to direct surgical attack. Unfortunately, in our experience, most of the poor surgical results have been associated with significantly impaired myocardial function. The patients present with evidence of congestive heart failure and since the mechanical factor (valve lesion) has been relieved, it is easier to obtain evidence of the true state of the myocardium. In some however, severe coronary artery disease is contributing to this malfunction, especially in older patients following aortic valve replacement. When isolated myocardial dysfunction is found, only intensive medical therapy can be offered.

———O———

your medical faculty at work

by John Sargeant
Executive Secretary

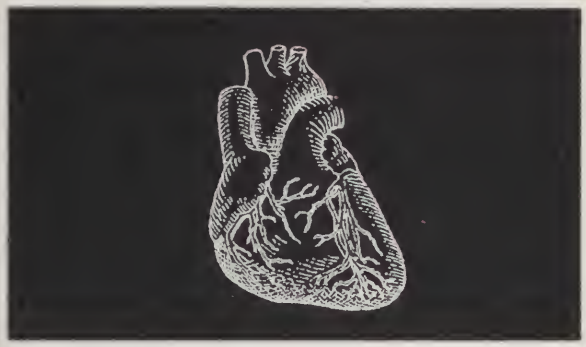
A special meeting of the Executive Committee was held December 19 during which the following actions were taken:

1. The following motion was adopted—

   "That the Executive Committee on behalf of the Faculty accept in principle the consideration of Blue Shield and the Physicians of Maryland underwriting the physicians' portion of the Medicaid Program in Maryland providing, following investigation, proper information and figures are brought back to this Committee, and to Council."

2. Authorized certain staff travel for 1969, pending adoption of the 1969 budget.
3. Authorized preparation of a statement to be presented at hearings before the U. S. Department of HEW in Washington, D. C. on December 30, 1968.
4. Authorized dispatch of a letter to the Mayor of Baltimore city urging that the City Health Commissioner be reappointed to that office for an additional term.

———O———



The Executive Committee at its January 9, 1969 meeting took the following actions:

1. Approved "copy" for an educational pamphlet on the Commission on Medical Discipline. This will be distributed to all members when printed.
2. Heard details of the Regional Meeting on Health Care Costs, sponsored by the U. S. Department of HEW in Harrisburg, Pa., and attended by the Faculty president.
3. Designated an "ad hoc" committee to be named by the President to investigate the legality of "consent" forms used by physicians; and the legality of treatment of "emancipated minors".
4. Declined to appeal a court order requiring the Faculty to permit a Judge to inspect records of the Faculty "In Camera".
5. Declined to provide legal defense for a physician not entitled to it because of late payment of dues even though he offered to underwrite the expenses in providing such a service.
6. Disbanded the Special Liaison Committee with the State Health Department and assumed the functions of this group.
7. Approved in principle the Health Resources Manpower Program as proposed by the Hospital Council of Maryland.
8. Approved the Guidelines for Citizens Service Award, as recommended by the Public Relations Committee.
9. Learned that no insurer for Professional Liability would cover a physician for any "punitive damages" award.
10. Referred to the Prince Georges County Medical Society the request from the Prince Georges Health Planning Council for comments on its preliminary study dealing with hospitals in that county.

(Continued next page)

11. Provided a nominee to the State Health Commissioner to be considered for his recommendation as an appointee to the Maryland Occupational Health and Safety Advisory Board.
12. Authorized transferring certain activities now conducted at the Presidential dinner to a House of Delegates session.
13. Designated a Faculty representative to the Administrative Committee of the Regional Medical Programs.
14. Authorized the President and President-Elect to name certain advisory groups in connection with the State Department of Health and Mental Hygiene budgets.
15. Stated it had no objection to a change in hospital licensure regulations which would not require a separate license for outpatient services on separate premises when operated by a hospital.
16. Authorized appointment of a special committee to consider the problem of Drug Abuse and Misuse.
17. Authorized representation and designated two persons to attend a meeting being sponsored by the AMA to discuss the JCAH revised standards for accreditation prior to their publication.
18. Declined to permit use of Osler Hall on the first Thursday of each month by the Baltimore City Medical Society because of other conflicts that evening, but suggested an alternate Thursday for the Society's use of the Hall.
19. Declined to be represented in an official capacity at the First National Conference on Abortion Laws.
20. Determined that no reply was necessary to a telegram from Wilbur J. Cohen, Secretary of the U. S. Department of HEW, which had urged physicians to use restraint on the charging of fees under Medicare, Part B; and requested patients to use restraint in the utilization of the services.
21. Authorized dispatch of a congratulatory letter to the Governor on his election and the offering of Faculty assistance.
22. Declined to underwrite the expenses of a member of the Emotional Health Committee to attend the Chicago National Conference on State Mental Health Representatives.

Pulmonary Function Testing in the Office

Formerly, pulmonary function testing was done primarily in larger institutions and was performed by physicians specially trained in pulmonary physiology. In recent years, testing has spread to smaller institutions and, in particular, to the physician's office. This has occurred largely as a result of increased awareness on the part of the physician (and the public) of the frequency of chronic bronchitis and emphysema and because of the commercial availability of relatively inexpensive pulmonary function testing equipment. This increase in the number of testing facilities is of importance because most pulmonary laboratories are set up for "in depth" studies and are not capable of handling a large patient load. Certainly any cigarette smoker who has a chronic productive cough or dyspnea should have the benefit of pulmonary function studies as a part of his evaluation. There is also good reason for periodically assessing ventilatory function in asymptomatic adult cigarette smokers in order to detect obstructive disease early. The physician's office is a logical place for such testing.

RICHARD W. BLIDE, MD
Assistant Professor of Medicine
Head, Pulmonary Laboratory
University of Maryland Hospital
and School of Medicine

With this development, pulmonary function testing and its interpretation have passed into the hands of physicians who have had little or no formal training in this area. This has resulted in problems relating to the use of pulmonary function equipment and the interpretation of results.

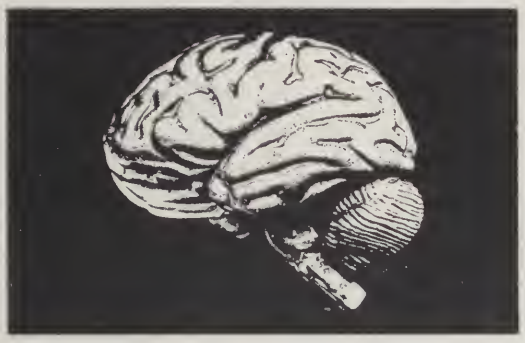
Many physicians in practice will at some time consider the advisability of obtaining pulmonary function testing equipment. For those who do not have specialized training in chest disease, it is recommended that the only piece of equipment obtained be a spirometer. Other types of testing require more technical skill and a more sophisticated knowledge of pulmonary physiology. Pulmonary laboratories can provide such studies when these are necessary.

Several spirometers are available and, in general, the quality is in proportion to the cost. One should look for a spirometer that is sturdy in construction, has a low apparatus resistance and is convenient to use. The paper speed should be sufficient to make accurate measurements and it should allow one to see changes in flow characteristics during forced expiration. These characteristics are one means of assessing the validity of the curve, and are masked if the paper speed is too slow.

Spirometry allows one to assess two types of ventilatory insufficiency: restrictive and obstruc-

tive. Restrictive ventilatory insufficiency is due to a loss of ventilable lung tissue. This may occur as a result of inflammation or fibrosis of the lung parenchyma, destruction or resection of lung tissue, heart failure, or chest wall disease (pleural, skeletal, muscular, or neurologic). A restrictive defect also occurs in emphysema and roughly parallels the loss in elastic recoil of the lungs as the destructive process progresses. The vital capacity gives a measure of this type of defect. The vital capacity is measured by having the patient inhale as deeply as possible and then exhale slowly until maximum effort results in no further flow. This value is then compared to that of normal individuals of the same age and height.[1]

Obstructive ventilatory insufficiency occurs when there is an increase in resistance to air flow within the bronchial tree. This may result from asthma, bronchitis or emphysema. It is usually measured in one of two ways. The forced vital capacity (FVC) is obtained as described for vital capacity but with the patient exerting a rapid maximal effort and forceably exhaling to the point of no flow. Although many measurements can be made from this curve, the most commonly used one is the forced expired volume during the first second (FEV1). The recorded value can be compared to predicted values.[1] The FEV1 can also be divided by the observed FVC, yielding the % forced expired volume in 1 second (FEV 1%). The latter value should be greater than 70%, and any lesser figure is indicative of obstructive disease. The maximum voluntary ventilation (MVV) can also be performed. This is obtained by having the patient breathe as vigorously and rapidly as possible for a period of approximately 15 seconds. Measurements from several sections of this tracing, of the volume exhaled, including 3 or more breaths, can then be made and converted to a figure representing volume per minute and compared to predicted values. The advantage of doing both the FEV1 and MVV lies in the fact that there is a good correlation between the two measurements. One can be used to check the validity of the other. The absolute value for the FEV1 $\times$ 40 should equal the MVV (plus or minus 10%). All studies should be repeated at least 3 times or until maximum values check within 5% of each other. Measurements should also be repeated after administration of a bronchodilator if the forced flow curve is abnormal.



The interpretation of spirometry requires experience and is difficult to discuss briefly. The article by Gaensler and Wright[1] gives a general guideline for the assessment of ventilatory function.

It should be appreciated that spirometry is not an objective test, although absolute numbers are obtained. The test results are influenced by the patient's volitional efforts. If this is not sufficiently great, the values will be submaximal and not indicative of the patient's true ventilatory function. It is important, therefore, to assess the patient's effort during the test, to encourage him to exert maximum effort, and to note when the effort is not adequate. When effort is submaximal, one has to be very careful in diagnosing ventilatory insufficiency rather than a lack of effort. Also, one should not make a diagnosis of ventilatory insufficiency or assess impairment on the basis of spirometry alone, or for that matter, solely on the basis of a battery of pulmonary function studies. The test results should always be correlated with clinical findings. When a discrepancy occurs between the pulmonary function studies and the clinical information, the test results should be questioned and repeated if necessary. As an example, the presence or absence of signs of airway obstruction, as determined by careful chest examination, correlates very well with the results of valid spirometry.

It is thought that the addition of the spirometer to the physician's office is of benefit. Physicians less experienced with this equipment should make every effort to perfect their testing techniques and to validate their test results and interpretations. Patients in whom abnormal spirometric records are obtained might be referred occasionally to a recognized pulmonary laboratory for a repeat study. Comparison of results could then be made and discrepancies resolved through discussion with the laboratory director. While the "under diagnosis" of emphysema and chronic bronchitis has occurred in the past, we are now starting to see the "over diagnosis" of these diseases and particularly the assessment of ventilatory insufficiency at a severer level than actually exists. The limitations as well as the advantages of spirometry should be appreciated.

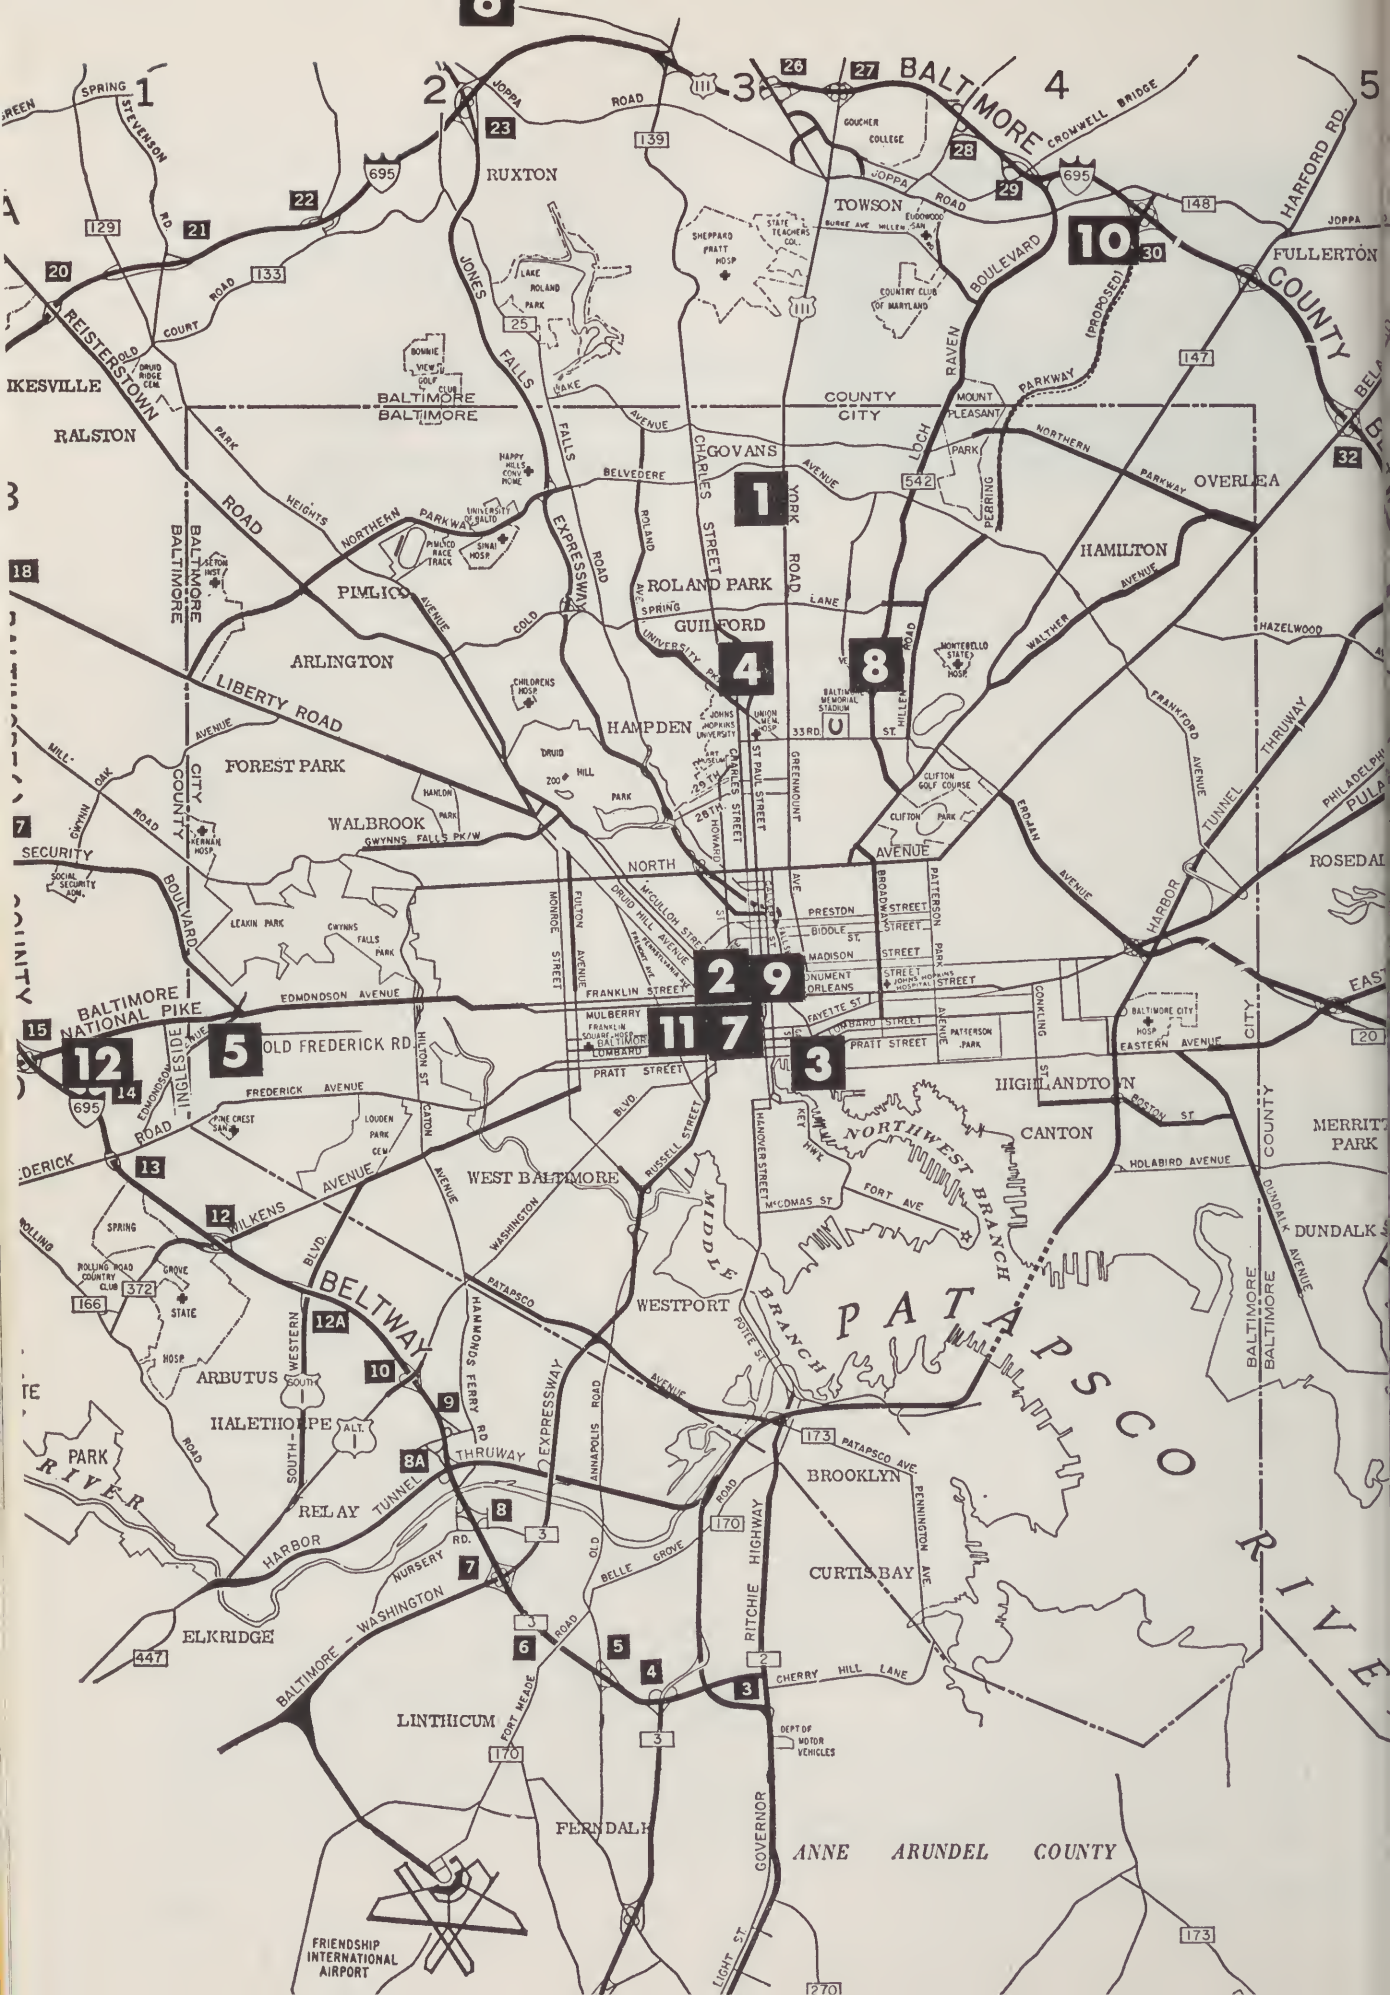
Voluntary Admissions

The number of patients who were self-admitted to Maryland's psychiatric hospitals reached a record 3,746 (or 33.8% of all admissions) during the 1967 fiscal year. Preliminary data for the twelve-month period ending June 30, 1968 indicate a further increase to 4,347, or 36.2% of that year's 11,997 admissions.



The following table shows that much of this rise is spurious and primarily reflects the rapid growth in admissions for the treatment of alcoholism. As indicated, the number of these patients has nearly tripled in the last five years and they now account for 46.6% of all admissions as compared with 28.7% in 1962. Alcoholics have a higher than average percentage of voluntary admissions. The increasing proportion of total admissions with this diagnosis has therefore produced a concomitant rise in the number and percentage of total voluntary admissions. Within each of the diagnostic categories shown, the proportion of self-admissions remained virtually unchanged between 1962 and 1967.

REPORTED PRIMARY DIAGNOSIS	NUMBER OF ADMISSIONS		PERCENT VOLUNTARY IN EACH DIAGNOSTIC GROUP	
	1967	*1962*	*1967*	*1962*
TOTAL ADMISSIONS	11,091	6,221	33.8	28.1
ALCOHOLISM	5,166	1,785	44.8	44.4
PSYCHONEUROTIC REACTIONS	700	424	52.7	52.8
OTHER PERSONALITY DISORDERS	723	410	23.2	34.4
SCHIZOPHRENIA	2,060	1,738	23.7	19.2
OTHER PSYCHOTIC DISORDERS	449	354	34.7	33.6
DISORDERS RELATED TO OLD AGE	678	730	6.8	5.9
MENTAL RETARDATION	144	157	11.1	10.2
ALL OTHERS	1,171	623	15.9	13.2

A number of other factors are also related to the relative frequency of voluntary admissions. Among these are:

1. PREVIOUS HOSPITALIZATION STATUS—30.5% of admissions with no reported prior psychiatric hospitalization and 36.4% of readmissions were voluntary. Excluding alcoholics, these percentages were reduced to 21.5 and 27.1, respectively.
2. RACE AND SEX—The percentage of voluntary admissions varied from 38.7 for white males to 33.1 for white females, 25.7 for nonwhite males and 26.6 for nonwhite females. This sex difference is mainly related to a seven to one male-female ratio in admissions for alcoholism. The racial variations, however, reflect a continuing greater use of the voluntary admission procedure by white residents.

Many individuals requiring psychiatric hospitalization have sufficient recognition of their illness to voluntarily accept treatment services. Since this initiative is considered to be a potentially positive factor in the treatment outcome, major efforts to encourage use of this procedure are warranted.

The AMBAR SCRAPBOOK of

Obesity Oddities

FACT & LEGEND

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg.,
phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety...helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

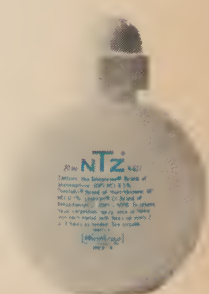
A. H. ROBINS COMPANY,
RICHMOND, VA. 23220

A·H·ROBINS

"The inconvenience of a cold"

For a cold, NTz® Nasal Spray provides rapid relief of nasal symptoms. Relief starts with the first spray which opens the inferior part of the common meatus. A second spray, a few minutes later, will shrink the turbinates to help provide sinus drainage and ventilation. Dosage may be repeated every three or four hours as needed, for temporary relief of symptoms. NTz is well tolerated but overdosage should be avoided.

As a sinusitis deterrent, NTz Nasal Spray can be used to keep the nasal passages open during a cold to help prevent development of acute sinusitis—or to help prevent the acute condition from becoming chronic.

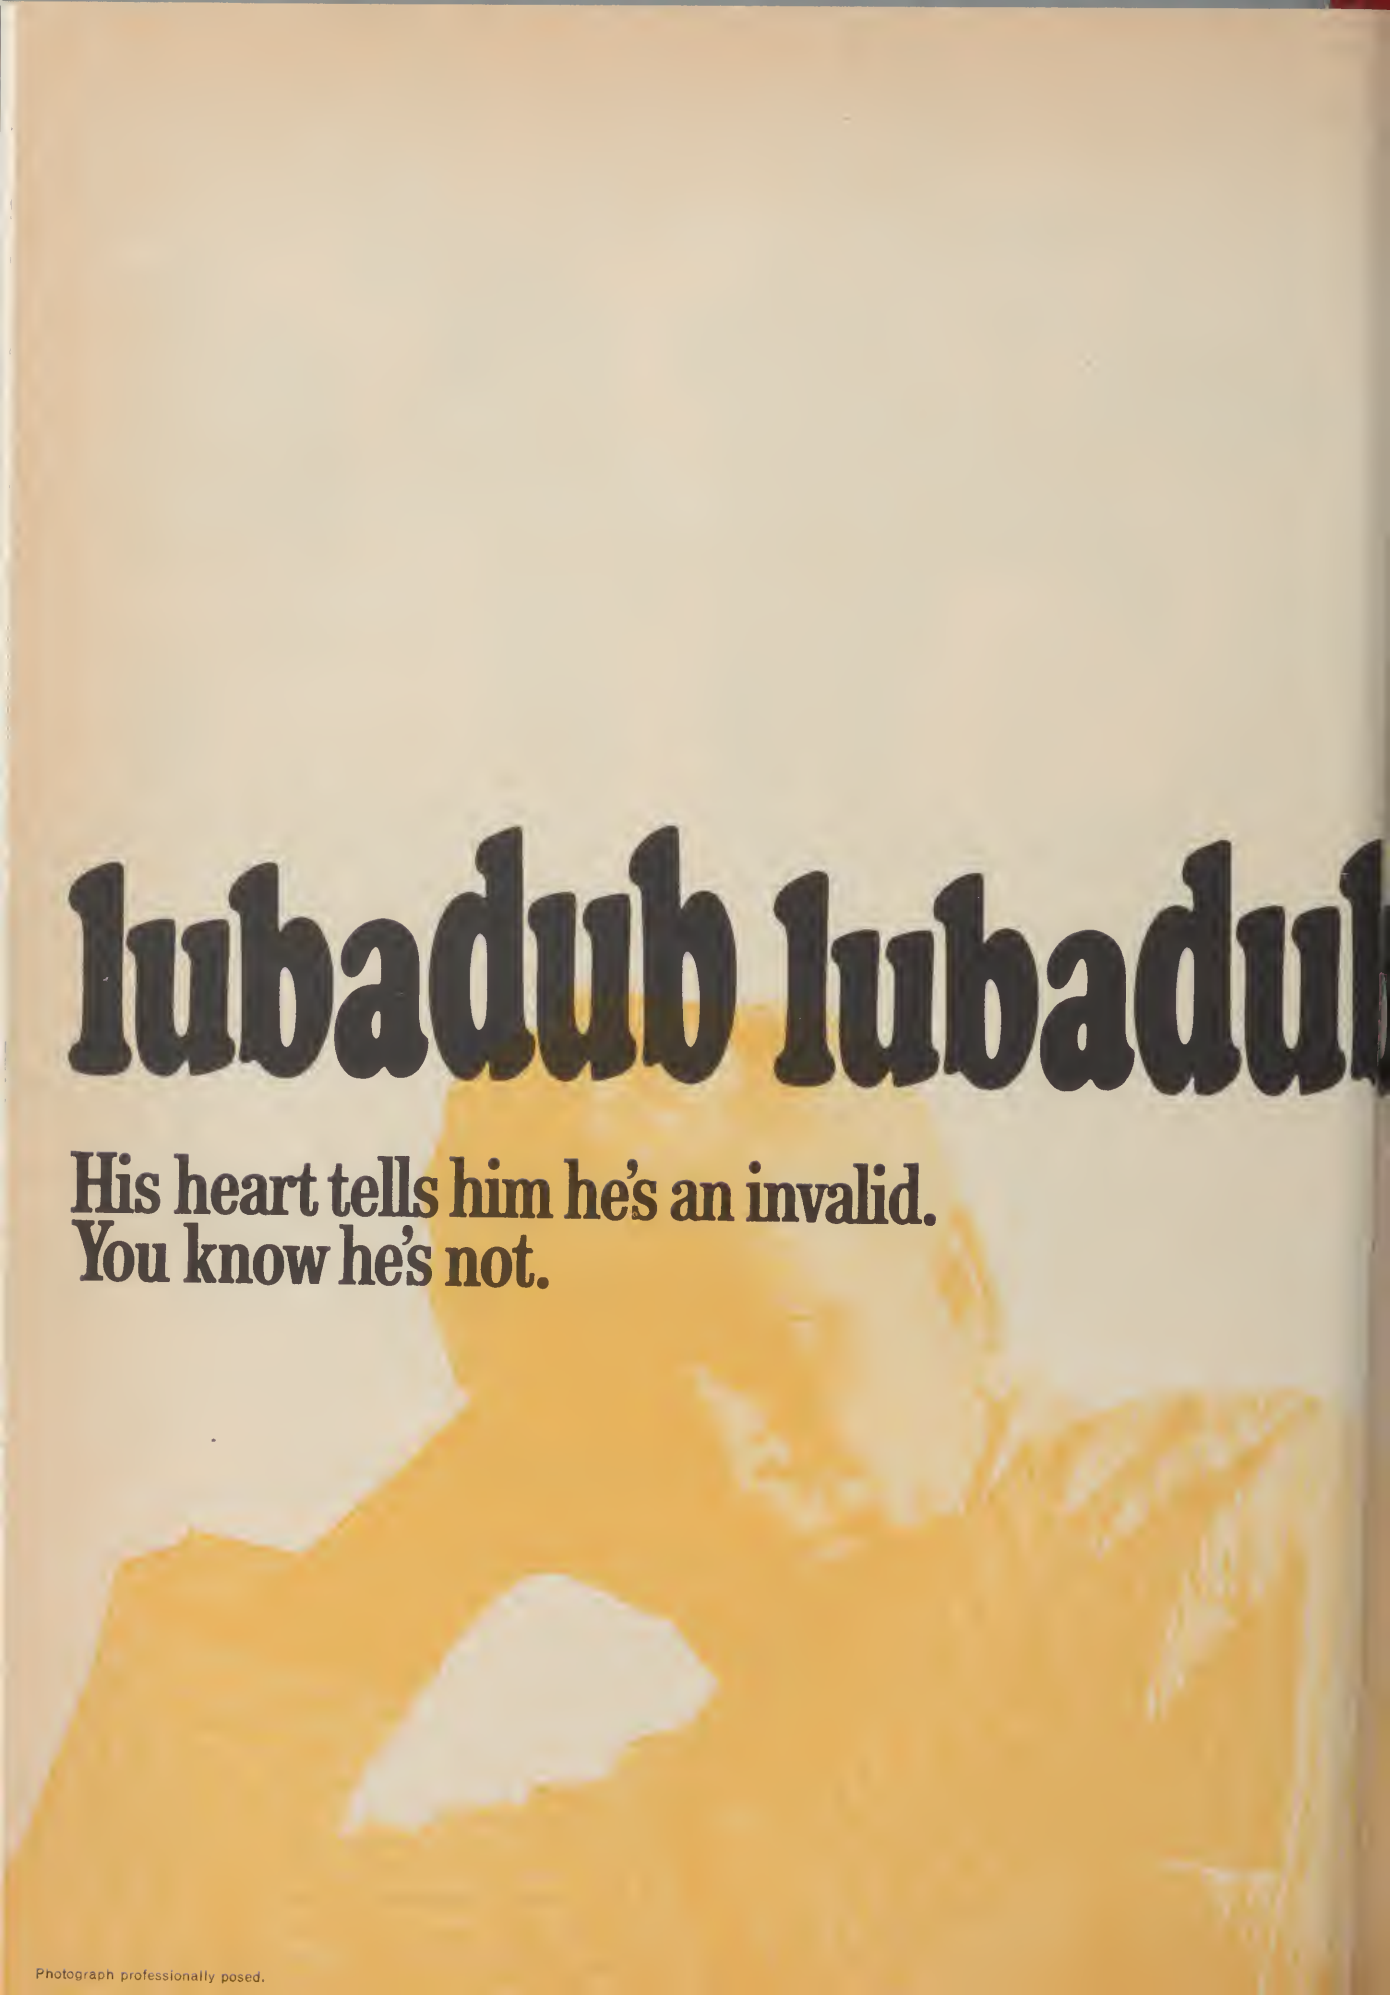


Supplied: NTz Nasal Spray, plastic squeeze bottles of 20 ml.; NTz Nasal Solution, bottles of 30 ml. (1 fl. oz.) with dropper.

NTz is more than a simple vasoconstrictor. It contains

Neo-Synephrine® (brand of phenylephrine) HCl 0.5 per cent, the major component, virtually synonymous with fast, efficient but gentle nasal vasoconstriction.

Thenfadil® (brand of thenyldiamine) HCl 0.1 per cent, topical antihistamine for reduction of rhinorrhea, sneezing or itching. It combats the allergic reactions that may occur in colds or sinusitis.



Zephiran® (brand of benzalkonium, as chloride, refined) 1:5000, antiseptic preservative and wetting agent to promote penetration and spread of the formula.

Winthrop Laboratories, New York, N.Y. 10016 Winthrop

lubadub lubadub

His heart tells him he's an invalid.
You know he's not.

Photograph professionally posed.

Contraindications: History of sensitivity to meprobamate.

Important Precautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use has been reported to result in dependence or habituation in susceptible persons, as alcoholics, ex-addicts, and other severe psychoneurotics. After prolonged excessive dosage, reduce dosage gradually to avoid possibly severe withdrawal reactions. Abrupt discontinuance of excessive doses has sometimes resulted in epileptiform seizures.

Warn patients of possible reduced alcohol tolerance, with resultant slowing of reaction time and impairment of judgment and coordination.

Reduce dose if drowsiness, ataxia or visual disturbance occurs; if persistent, patients should not operate vehicles or dangerous machinery.

Side Effects include drowsiness, usually transient; if persistent and associated with ataxia, usually responds to dose reduction; occasionally concomitant CNS stimulants (amphetamine, mephentermine sulfate) are desirable. Allergic or idiosyncratic reactions are rare, but such reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Previous history of allergy may or may not be related to incidence of reactions. Mild reactions are characterized by itchy urticarial or erythematous maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis,

ibadubdub lubadi

Anxiety is expected in the cardiovascular patient. A little may even be desirable.

But when anxiety is exaggerated . . . when it interferes with sleep . . . when it aggravates cardiovascular symptoms, your help may be needed.

Naturally, you'll want to reassure the patient.

And perhaps prescribe Equanil (meprobamate) as adjunctive therapy. It helps relieve anxiety and tension specifically, yet gently.

Almost 15 years' use has shown that Equanil is usually well tolerated as well as effective. Side effects are generally limited to transient drowsiness; serious, therapy-interrupting side effects are rare.

stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically as with epinephrine, antihistamine and possibly hydrocortisone. Aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia have occurred rarely, almost always in presence of known toxic agents. A few cases of leukopenia, usually transient, have been reported on continuous administration.

Meprobamate may sometimes precipitate grand mal attacks in patients susceptible to both grand and petit mal. Extremely large doses can produce rhythmic fast activity in the cortical pattern. Impairment of accommodation and visual acuity has been reported rarely. After excessive dosage for weeks or months, withdraw gradually (1 or 2 weeks) to avoid recurrence of pretreatment symptoms (insomnia, severe anxiety, anorexia). Abrupt discontinuance of excessive doses has sometimes resulted in vomiting, ataxia, tremors, muscle twitching and epileptiform seizures. Prescribe very cautiously and in small amounts for patients with suicidal tendencies. Suicidal attempts have resulted in coma, shock, vasomotor and respiratory collapse and anuria. Excessive doses have resulted in prompt sleep; reduction of blood pressure, pulse and respiratory rates to basal levels; and occasionally hyperventilation. Treat with immediate gastric lavage and appropriate symptomatic therapy. (CNS stimulants and pressor amines as indicated.) Doses above 2400 mg./day are not recommended.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. (All tablets also available in REDIPAK® [strip pack], Wyeth.) Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

Wyeth Laboratories Philadelphia, Pa.

Equanil®
(meprobamate) Wyeth®

The two-stage power of the pink pill for U.R.I. symptoms is nothing to be sneezed at.

The immediate and continuous-release actions built into each Novahistine Singlet can give most of your patients prompt and long-lasting relief from symptoms of upper respiratory infection, including fever, aches and pains. Not only does Novahistine Singlet provide a vasoconstrictor-antihistamine formulation to reduce congestion and help restore normal ciliary activity; it also contains an antipyretic-analgesic compound to relieve the fever, aches and pains that so frequently accompany upper respiratory infections. A total daily dosage of 3 or 4 tablets will normally provide the continuous relief your patient expects. Use with caution in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

Pitman-Moore Division of
The Dow Chemical Company,
Indianapolis, Indiana.

Novahistine®
Singlet decongestant-analgesic

(Each tablet contains: phenylephrine hydrochloride, 40 mg.; chlorpheniramine maleate, 8 mg.; acetaminophen, 500 mg.)

MEMO

To: The Medical Profession

From: Don P.

Re: A View From the Bottom of the Bottle

As a recovered alcoholic, I spend a lot of time working with other alcoholics and I have heard many stories of their encounters with the medical profession. Except in a few cases, such encounters do not result in the alcoholic's receiving meaningful help. I have frequently encountered the medical profession myself and have gotten no help with my alcoholism.

The medical profession is not alone in its failure to cope with the illness of alcoholism. Society as a whole fails consistently to identify the alcoholic and motivate him toward help. As practicing alcoholics reap the penalties of their uncontrolled drinking, they frequently collide with society. Virtually every collision creates a crisis situation that finds the alcoholic particularly vulnerable to motivation. But, professional "con artists" that we alcoholics are, we generally escape with a warning, a fine, a wave of the finger, a pat on the head, or a prescription, and without the help we need.

Why does society fail to capitalize on opportunities to motivate alcoholics? In the great majority of cases, failure occurs not out of malice, but out of ignorance. Many failures result also from preconceived prejudices toward alcoholics stemming from painful or unfortunate past experiences reaching as far back as childhood.

Many, many people in excellent positions to help alcoholics fail to recognize them or, recognizing them, do not know enough about the illness to provide meaningful help. Law enforcement officers, judges, lawyers, ministers, social and welfare workers, families and, yes, doctors and nurses encounter alcoholics during crisis situations and, more often than not, they fail to recognize or help these sick and desperate people.

Alcoholics consult physicians for a variety of physical and mental complaints which, most often, directly or indirectly, relate to alcoholism. The medical profession is in an excellent position to wave the red flag in the faces of developing alcoholics, but, too frequently, they fail to do so.

I have heard many recovering alcoholics talk of their first encounters with family physicians over the amount of alcoholic beverages consumed. In many cases, the alcoholics were honest, but usually the advice they received was, "Cut it down to one or two a night;" or, "Leave the hard stuff alone—just drink beer;" or a very abrupt, "Stop." Obviously none of these suggestions may be considered treatment of the illness of alcoholism. Even the admonition "Stop," which is what alcoholics must eventually obey, needs to be accompanied by education, therapy and encouragement so that the *need* for alcohol is eliminated.

How often does the average practicing physician encounter alcoholics among his patients? If the incidence rate is 3%, I suggest that at least 5% of the patients a general practitioner treats are alcoholics. Why the higher rate? Because alcoholics are much more susceptible to other illnesses, I assume they make more frequent trips to their family physicians than nonalcoholics. I believe that if a general practitioner sees an average of 200 patients a week, at least ten of them are alcoholics. It would be interesting to know how many alcoholics are diagnosed and, more importantly, how many are appropriately treated.

Many doctors resort to tranquilizers as an aid to alcoholics in stopping or cutting down their consumption of alcohol, a potentially dangerous practice. In many cases, alcoholics, particularly those in the late stage of the illness, will need medication during withdrawal. However, doctors should be aware that they are dealing with individuals with "addictive" personalities. It is terribly easy for alcoholics to become "hung-up" on medications in addition to alcohol. I have met many alcoholics who were also addicted to some sort of medication, and the results can be and frequently are disasterous.

As an example, one 27-year-old alcoholic I have worked with for more than a year has had a very difficult time. He is quite sincere in his effort to recover. Unfortunately, he is an impulsive individual and, on the spur of the moment, he will take that first drink which always leads to a three or four day binge. His last binge took him to a State hospital. The staff there, after careful consideration of his history and physical condition, recommended Antabuse. As soon as he was released, he obediently (and with new hope) went to his family doctor for a prescription for Antabuse. The doctor refused to give him a prescription on the grounds that he would not prescribe any drug that might be harmful. He would, however, put him on tranquilizers. Fortunately, my young friend had beter sense about alcoholism and refused the offer. He is now on Antabuse and progressing nicely.

My own experience with the family physician was interesting. After having been sober for about one year, I told him I was an alcoholic. I also told him that in the event he encountered alcoholics in his practice, I would be happy to talk with them on his referral. My offer angered him and he quickly assured me that alcoholics need *medical* attention. I agreed and dropped the subject. I hate to think this otherwise brilliant young doctor feared that I would somehow cut into his rightful domain if I tried to complement his treatment of alcoholics.

The physicians in the two examples above, I hope you will agree, do not know enough about the illness of alcoholism. To be perfectly fair, we can't hold them, and others like them, entirely responsible. After all, until just the last couple of years medical schools were offering little meaningful education about this illness. A medical friend has told me that if a doctor is over 35, he has probably received no more than one or two hours education on alcoholism, the illness that ranks third on the list of public health problems. I heard another doctor say that his one hour lecture on alcoholism in medical school consisted of detailed instructions on how to get a "drunk" out of the waiting room without disturbing the other patients. Is this the most we can expect from our medical schools and their graduates?

Many doctors will complain about their lack of success in treating alcoholics. The term "poorly motivated" is frequently used in talking about their alcoholic patients. In all too many cases, alcoholics are faced with "poor motivators," but physicians find it easier to blame the poor patients, discharge them and let them drift toward premature death or insanity. Quite frequently the problem with doctors who fall into this category is that they attempt to treat alcoholism and the alcoholic independently, without referring to other kinds of services. They fail to understand the complexities of an illness that often requires a wide variety of professional help.

As noted above, the illness of alcoholism is ranked as the third public health problem. I suspect it should be ranked higher. If the true mortality rate were known it might rise to number one. But again, many well-meaning doctors cloud the issue and "protect" the family by listing on death certificates some secondary condition caused by the alcoholism. I fear they have the still prevalent

attitude that alcoholism is somehow a dirty word. When will the medical profession stop giving only lip service to the AMA's own statement ten years ago that alcoholism is a disease?

Needed to correct this deplorable condition is education at all levels. First, meaningful education must be included in all medical schools. Secondly, doctors already in the field must be urged to learn as much about the illness as possible, and about the other community resources that can be brought to bear on the complex problems of the alcoholic patient. Physicians must learn that they should share the alcoholic's recovery program with other disciplines. In order to do this they must become familiar with other disciplines.

General hospitals must be urged to offer in-patient detoxification treatment. The acutely intoxicated alcoholic is a person who requires close medical attention to insure that withdrawal from alcohol is not fatal. Too many have died in the gutters, in drunk tanks or in state institutions because community hospitals have discriminated against them.

The medical profession must participate in and contribute to a continuing dialogue on alcoholism with all disciplines concerned about the illness. Such exchange of knowledge and experience will enhance the effectiveness of all those working in the field.

Finally, the medical profession might very well consider the role of specialization in this area. With 6,000,000 alcoholic patients waiting to be helped, an enormous need exists, and specialists can ease the burden on already overburdened general practitioners.

Not all my suggestions will be adopted overnight. And, in the meantime, my frustration will continue, at least for a while, particularly when I think of the 10,000,000 alcoholics who may have died premature deaths over the past twenty years. While their death certificates may not show alcoholism, the real cause of their deaths can be assumed. Is it any wonder that anger boils up when I ask someone to help an alcoholic and I get a shrug of the shoulders or the reply, "Why?" I hear 10,000,000 buried reasons cry back, "Why not?" I pray that physicians will hear the cry for help from the alcoholics still alive, with potential for recovery.

OBETROL®
for weight control

Each OBETROL-10 tablet contains: Methamphetamine Saccharate 2.5 mg.; Methamphetamine Hydrochloride 2.5 mg.; Amphetamine Sulfate 2.5 mg.; Dextro-amphetamine Sulfate 2.5 mg.; (OBETROL-20 tablets contain twice this potency) Pat. #2748052.

This combination of amphetamines may be useful as an adjunct in the management of certain forms of obesity where an appetite depressant is indicated.

Contraindications: Hypertension, advanced arteriosclerosis, coronary artery disease, cardiac arrhythmias, peripheral vascular disease, states of undue restlessness, anxiety, excitement, agitated depression, hyperthyroidism, idiosyncrasy to amphetamine, concomitant administration of a monoamine oxidase inhibitor. **Precautions:** Use with caution in individuals with anorexia, insomnia, vasomotor instability, asthenia, psychopathic personality, a history of homicidal or suicidal tendencies, and individuals who are known to be hyperractive to sympathomimetic agents, or emotionally unstable individuals who are known to be susceptible to drug abuse. Certain monoamine oxidase inhibitors may potentiate the action of Obetrol. **Side Effects:** The most common side effects attended with the use of amphetamines include nervousness, excitability, euphoria, insomnia, dryness of mouth, nausea, vertigo, constipation, and headache.

Dosage and Administration: Initial adult dose is one-half to one 'Obetrol-10' tablet daily, preferably one-half to one hour before meals. This may be gradually increased to one 'Obetrol-10' or 'Obetrol-20' tablet one to three times daily as indicated. **Supplied:** Tablets scored, in bottles of 100. 500, and 1000.

rehabilitation notes

Prediction of Performance of Patients with Hip Fracture. #2

"Those who love seldom fail; but our predictability may fail—graphs, charts, formulae—these all may fail. For we know only in part—as yet we have but peep-holes into realities—and we predict only in part; there is always the unpredicted. And when we know more, that which is a part will become obsolete and should be done away with or revised."

Corinthians 1, 13:8. (William Pemberton)

* * * * *

A previous report[1] of 150 hip fractures identified some important findings at initial evaluation which are helpful in the prediction of future perfomance of Activities of Daily Living. A Prognostic Index and score method was presented as a semi-quantitative method of predicting future performance. In this communication, we wish to test the statistical predictors derived from the 150 cases on an entirely new group of 76 patients with hip fracture to see how helpful the data derived from the 150 cases is in predicting results of treatment in the 76 new cases.

Prognostic Index and Score

The weighted values for various initial findings (age, sex, duration, MSCL, and ADL scores, medical prognosis, and diagnostic group) derived from the first 150 cases of hip fracture have been applied to the second group of 76 cases. Table I shows that 98% of the new group of patients with prognostic scores of four or less improved, whereas only 54% of those with scores over four improved. As the prognostic score increased, both the percentage improving and the degree of improvement decreased.

Discriminate Analysis

Discriminate function coefficients were derived from the initial group of 146 cases (four cases could not be used) for age, duration, prognostic group, MSCL and ADL score and diagnostic group and appropriately applied to the second group of 76 patients to derive Z.[2] The patients were then placed in the appropriate final ADL Groups ranked in order and compared with the rank derived from the Prognostic Index Score. Comparison of the ranks derived from the discriminate analysis and from Prognostic Score showed no significant difference. We conclude that discriminate analysis has no advantages for prognostic purposes over the Prognostic Index in this series.

TABLE 1

Prognostic scores derived from previous series (150 cases) applied to new series (76 cases).

Prognostic Score Calculated at Initial Evaluation	Total Cases	Reached Full Independence ADL Score 100	Reached ADL Score 90-99	Reached ADL Score less than 90	Unchanged ADL Score	Deteriorated or Died
0	5	1	3	1		
1	11	6	4	1		
2	8	3	2	3		
3	2	2				
4	13	7	2	3	1	
5	5		2	2	1	
6	3		2	—	1	
7	5		3	1	1	
8	3	1			1	1
9	4	1		2	1	
10	4			2	2	
11	3			2	1	
12	4			2	1	1
13	2				2	
14	2				2	
15	2				1	1
Total	76					

Correlation Coefficient

As with discriminate analysis, correlations of coefficient matrix are not strictly applicable to ordinal scales. Except to confirm that the final ADL score group was strongly influenced by age, MSCL and ADL scores, little came out of this analysis.

Summary

Elaborate statistical methods do not yield information of prognostic value in our patients with hip fracture superior to the Prognostic Index as described previously.[2] However, there is no assurance that a Prognostic Index worked out for one hospital will apply to another, nor that there may not be subtle changes in the selection of patients invalidating the Prognostic Index in the same hospital with time.

Baltimore City health department

"Your Family Doctor" Celebrates 20 Years On TV

On December 22, 1968 the jointly sponsored "Your Family Doctor" television series produced by the Baltimore City Health Department and the Medical and Chirurgical Faculty celebrated its 20th year on WMAR-TV.

The series, inaugurated December 18, 1948, is not only the oldest continuously produced medical-health television program series but also has one of the longest consecutive runs for a television series of any type—the anniversary program being number 1,005. Additionally it can be said that the Medical Faculty and the City Health Department had the foresight to recognize the great potential of TV in health education at that early date and there is no doubt that this series has contributed immeasurably to the successful health drives conducted through the years and to the health of the citizens of our city and state.

Joining in the anniversary program commemorating the program's years of service and rededication were Emerson R. Julian, MD, chairman of the health committee of the Baltimore City Council, who represented the Mayor; Arthur G. Siwinski, MD, President of the Medical Faculty; Huntington Williams, MD, former Commissioner of Health of Baltimore City (retired) who was instrumental in the establishment of the program; Robert E. Farber, MD, present Commissioner of Health, and Mr. Robert B. Cochrane, Assistant General Manager of the station.

The following is from the anniversary telecast titled "Souvenirs of 20 Years." Dr. Worthington, played by Jack Redfern, Chief of Community Health Information is named for Baltimore's first Health Officer, Dr. John Worthington, appointed by Governor Thomas Sim Lee in 1792 to help prevent the spread of yellow fever from Philadelphia to Baltimore.

DR. WORTHINGTON: Today we are going to have a look at some of the television souvenirs of 20 years and my first guest is Dr. Huntington Williams, retired Commissioner of Health of Baltimore City.

Dr. Williams, in your 30 years as Commissioner of Health you were a strong advocate of health education, would you tell us about the beginnings of the "Your Family Doctor" series?

DR. WILLIAMS: Yes, Dr. Worthington. During those 30 years it was my belief that public health can only be successful if people know what is being done by their health department and what they can do about their own individual health. So we devised a program with five basic aims which are: (1) to promote an understanding of how to keep well, (2) to encourage consultation with the family doctor, (3) to present public health problems, (4) to inform the public of City Health Department activities, and (5) to demonstrate how the family physician and the health department work together.

To carry out these ideas we ran a weekly radio series which began in January 1932. With the advent of television and shortly after WMAR-TV first opened we began the weekly telecast of a similar program on December 15, 1948. That

makes this the oldest continuous medical TV program in the world. The first program had as its guests the father of our present Mayor of Baltimore, Mayor Thomas J. D'Alesandro, Jr.; Dr. Charles Maxson, the President of the Medical and Chirurgical Faculty of Maryland; Dr. Walter D. Wise, Chairman of the Faculty Council and myself. The Mayor at that time stated, "I am glad to see that these new efforts are being made to bring health instruction to the people and would thank the physicians of Maryland and the officials of the television station for their interest and support."

DR. WORTHINGTON: The program was, then, as successful as hoped.

DR. WILLIAMS: Indeed so, its influence went far beyond just citizens of Baltimore and Maryland. In 1952 it received an award from the Institute of Educational and TV Programs, Ohio State University at the 16th American Exhibition of Educational Radio and TV Programs. Here is the award as shown by Mr. Robert Cochrane of WMAR-TV to Mr. Gordon, Director of our Bureau of Health Information, Dr. George Yeager of the Medical and Chirurgical Faculty and me. This demonstrates the program's ability to have an effect far beyond the mere confines of the local area covered by this TV station. Practically every year some organization or other either in or outside the United States sends for information on how to do similar TV programs. Two years ago films of the Family Doctor program were used for a symposium for health officers and physicians in Canada to encourage the use of TV for public health education there. From time to time foreign students from The Johns Hopkins School of Hygiene and Public Health have come to perform on the program or to observe and learn, then have returned to their countries with an increased admiration of the value of educational TV in promoting health. What's more, the program is well known to the officials of the World Health Organization. One of them, Dr. Lennart Hesselvik, did one program with us in 1958 and, of course, we have worked in close cooperation with the World Health Organization all the years the program has been on. So we can say that "Your Family Doctor" has exceeded our greatest expectations.

DR. WORTHINGTON: Thank you, Dr. Williams, and now I would like to talk next to Dr. Arthur Siwinski, President of the Medical and Chirurgical Faculty of Maryland. Dr. Siwinski as cosponsor of the "Family Doctor" program the Medical and Chirurgical Faculty has certainly assisted greatly in many ways to provide the public with health education.

DR. SIWINSKI: Yes, many of the guests on the program are drawn from the Faculty and sometimes props are borrowed from our Medical Museum, but I would like to speak of some of the state-wide programs of preventive medicine in which this series has played a large part.

DR. WORTHINGTON: First of these was the Salk Polio Campaign, wasn't it?

DR. SIWINSKI: Yes, Dr. Worthington. Polio was a major health problem in those days, and when Jonas Salk developed a preventive vaccine, it was necessary to inform the public of what was needed to prevent this disease. The mass media were used extensively and the "Family Doctor" program made an important contribution to the success of the program.

DR. WORTHINGTON: Another preventive medicine campaign on the "Family Doctor" program has been the annual Diabetes Detection Drive.

DR. SIWINSKI: True, Dr. Abraham Silver, has been very active in the Medical Society's efforts to detect unknown diabetes. The "Family Doctor" program has helped to promote a sizable turnout for the tests.

On an even larger scale was the state-wide Sabin Oral Polio Vaccine Drive in 1963 in which the "Family Doctor" program and WMAR-TV showed the public how easy it is to get protected against polio. The success of this drive is pointed out by the almost complete eradication of polio in our state.

Then a few years ago the "Family Doctor" took an active part in promoting rabies vaccination in a large portion of Maryland. This campaign was conducted in cooperation with the Maryland Veterinarian Association.

Recently the "Family Doctor" program aided in the state-wide measles vaccination campaign conducted by the Medical Society and the Health Department. This is one of several TV programs presented by "Your Family Doctor". Appearing on this program were Dr. Edward Davens of the Maryland State Department of Health and Dr. Robert E. Farber, the present Commissioner of Health of Baltimore. In short, this TV series has proven a valuable tool in assisting physicians and health officers to attack large problems of

preventive medicine by bringing large scale public cooperation.

DR. WORTHINGTON: Thank you, Dr. Siwinski. Our next guest is the present Commissioner of Health of Baltimore City, Dr. Robert E. Farber. Dr. Farber, although the program was presented principally as teamwork with the private physician, I think you'll agree that an increasing amount of attention has been paid to those health workers who are not physicians.

DR. FARBER: Yes, over the years the Health Department's objective of maintaining and improving the health of the people has increasingly required the assistance of those outside the medical profession. Today we need more sanitarians, nurses, health and social agency workers, and safety engineers to solve many of our health problems. So more recently the "Family Doctor" program has included such guests as members of the Maryland Pharmaceutical Association to talk about safe use of drugs and the problem of drug abuse. On other occasions, the program has been used to recruit young people into careers in the health field. For example, here is a program to recruit more student nurses and there have been similar programs promoting careers in physical therapy, medical technology, dietetics, social work and dental and environmental hygiene.

DR. WORTHINGTON: Of course, this does not mean that the physician has been left out.

DR. FARBER: Not at all. The physician has been consistently called upon to be an educator in preventive medicine. Here is Dr. Allen Voshell explaining the function of the bones of the body, the diseases and injuries that can occur to them and how to prevent or treat such disease and injury.

DR. WORTHINGTON: But in meeting Baltimore's health problems the importance of a team effort must not be overlooked.

DR. FARBER: Yes. Perhaps the best example of this is the problem of preventing child lead paint poisoning which has required not only the physician but many others outside the medical profession to bring about public recognition that lead poisoning in our city is a health problem that each citizen can help eliminate. Here one of our former health officers, Dr. H. Maceo Williams, is discussing the matter on the Family Doctor. It is through the efforts of the mass media, including TV programs like this that has helped to reduce the deaths of Baltimore children from this cause.

DR. WORTHINGTON: Sometimes we tend to forget that the promotion of safety is an important part of maintaining public health too.

DR. FARBER: That's true, Dr. Worthington, but throughout the years the "Family Doctor" program has provided viewers with consistent reminders of the importance of safety in maintaining health.

Here is a show from last year's Christmas season in which Captain McLaughlin of Baltimore's Fire Prevention Bureau demonstrated some danger spots around the home at Christmas time. Other subjects done in cooperation with health agencies are motoring and pedestrian safety, prevention of falls, poison prevention, camping safety, swimming and boating safety, hunting and firearm safety, and eye safety. Thus, the "Family Doctor" TV series has contributed greatly in bringing together in a close working relationship the physician and those outside the medical profession in meeting the City's problems of public health and safety.

DR. WORTHINGTON: Thank you, Dr. Farber. And now it is my pleasure to call on Dr. Emerson R. Julian, Chairman of the health committee of the Baltimore City Council, who is representing the Mayor. III to close our program today.

DR. JULIAN: Thank you, Dr. Worthington. In the betterment of the disadvantaged this series has given public information on the Model Cities Program, the Park Heights Adolescent Project, the work of the Bureau of Special Home Services and as seen here even has involved an entire cast from Morgan State College in the production of a program concerning one of our serious public health problems—tuberculosis. Its annual support of the Spring Clean-up Campaign and Fire Prevention Week won the City Health Department an award this year from the Fire Department. So the program has been at least partially responsible for our Fire Prevention Bureau's high rating among the largest cities of the United States. I might also add that the programs on poison prevention contributed to Baltimore's winning the National Safety Council's "Flame of Life" award some three years ago. But these are past honors. I am informed that "Your Family Doctor" is planning support for a major effort toward solving inner city health problems such as malnutrition and sanitation, and I have high hopes that in these efforts it will be as successful as it has in past campaigns. So at this time I would like to thank the physicians of Maryland for their sup-

port of this television series and as spokesman for all concerned with the production of the "Your Family Doctor" series to offer to Mr. Robert B. Cochrane, Assistant General Manager of WMAR-TV, this plaque in tribute to the 20 years of public service rendered by the staff of this station.

The wording is as follows: *"To WMAR-TV for 20 years of public education in preventive medicine, public health and safety on the weekly TV series, "Your Family Doctor"—The Baltimore City Health Department and the Medical and Chirurgical Faculty of Maryland."*

MR. COCHRANE: Thank you very much, Dr. Julian. I accept this on behalf of WMAR-TV with a pleasure as unique as the program itself. I don't think many programs in all of television can boast a record of 20 years and more than a thousand telecasts and I believe its value in medical education and medical information to the community has been incalculable. Thank you very much.

Following Mr. Cochrane's acceptance the program was concluded in the usual fashion by Dr. Worthington thanking his guests and the program sign-off reminder to viewers to "Remember to learn to do your part in the prevention of disease."

"Your Family Doctor" is prepared and coordinated by the Bureau of Health Information in the Baltimore City Health Department guided by a TV Committee comprised of both Health Department and Medical Faculty members. Scripts are written by Mr. John Stidman of the WMAR-TV staff. Production is supervised by Mr. Joseph Gordon, Director of the Bureau of Health Information and Mr. Jack Redfern.

Opportunity is afforded here to extend gratitude to the many physicians and health workers who have cooperated through the years in this unique health education series.

The Art of Medicine

"The art has three factors, the disease, the patient, the physician. The physician is the servant of the art. The patient must cooperate with the physician in combating the disease."

Hippocrates "Epidemics"

This quotation is one of the eternally true statements of Hippocrates, as evidenced by these titles:

The human side and the business side of medical practice. (AMA); Patients and their doctors. (Cartwright); The doctor, his patient, and the illness. (Balint); The management of the doctor-patient relationship. (Blum); Privileged communications between physician and patient. (DeWitt); Death and dying; attitudes of patient and doctor; The psychology of medical practice. (Hollender); The doctor, his career, his business, his human relations. (Truman); The changing patient-doctor relationship. (Vorhaus).

MRS. HARRY L. BERMAN, EDITOR

National President to Install Officers in April

Mrs. Clifton C. Long, National President of the Woman's Auxiliary to the AMA, has graciously accepted our invitation to address our Annual Meeting and install our incoming officers on April 10, 1969, at the Belvedere Hotel. Do plan ahead to join us in welcoming Esther. Mark your calendars now.

Mrs. Long of Ozark, Arkansas was installed as president of the Woman's Auxiliary to the American Medical Association at the 45th annual convention in June 1968, in San Francisco, California, after completing her term as president-elect. She has contributed to the national auxiliary since 1961 when she was southern regional health careers chairman. She served three years as national rural health chairman, 1962-64, and two years as a first vice president, 1965-67.

On the state level, she has held various chairmanships including community service, legislation, program and safety. She served as state president in 1960-61, and also was president of her county auxiliary.

Esther Callahan attended Topeka, Kansas, grade and high schools, Washburn College and Kansas University, where she met and married Clifton C. Long in 1940. While he attended medical school at the University of Arkansas, Mrs. Long worked as a secretary to the anatomy and chemistry departments at the school.

Dr. Long is an abdominal surgeon and chief of staff at the Turner Memorial Hospital in Ozark. At the present time he is a city alderman and on the local school board.

Mrs. Long

Dr. and Mrs. Long have four children: Cliff III, age 24 (married), is a student at Arkansas Tech School of Business, majoring in hospital administration; Mary (Mrs. James L. Gardner), 22, recently received a degree in elementary education from Southeastern Louisiana College; Joan, 18, has just graduated from Ozark High School and is interested in the medical field, and June, 16, is a junior at Ozark High School.

Mrs. Long has served her community as PTA president, WSCS president and chairman, Garden Club president and Community Improvement chairman. She was selected as Citizen of the Year in 1956 for Ozark, named life member to the WSCS of the Methodist Church, named Arkansas Woman of the Year in 1964 by the *Progressive Farmer,* and awarded the honorary degree of the Chapter Farmer by the Ozark FFA in 1964. She was responsible for starting brownie, girl scout and cub scout programs in Ozark, and served as leader for all of the groups in past years. She was appointed to the Board of the Arkansas Training School for Girls in 1961, serving as vice-chairman of the Arkansas Juvenile Training School Board which governs all training schools for delinquent children in the state. In 1968 she was appointed to the Arkansas Commission on the Status of Women.

We are most appreciative of Esther's tireless efforts on behalf of medical society auxiliaries throughout the country, and especially of her willingness to travel so far to be with us. Let's all give her the tribute she deserves by turning out to hear her in April.

You've made it one of your specifics in acute otitis media

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

You've made it one of your specific in acute otitis media

DECLOMYCIN acts against many strains of H. influenzae, pneumococci and streptococci, the most common invaders. In otitis media, where it is difficult to isolate the causative organism, this coverage may be important. However, some strain may be resistant and other pathogens can be involved.

You've found the high serum levels of DECLOMYCIN important, too. Its prolonged actio permits convenient 300 mg b.i.d. or 150 mg q.i.d. administration.

When specimens are obtainable, your culture studies will indicate the usefulness of DECLOMYCIN.

Effectiveness: DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines in infections caused by organisms sensitive to the tetracyclines.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocol pruritus ani. Skin—maculopapular and erythematous rashes; a ra case of exfoliative dermatitis has been reported. Photosensitivit onycholysis and discoloration of the nails (rare). Kidney—rise in BUN apparently dose-related. Transient increase in urinary output, some times accompanied by thirst (rare). Hypersensitivity reactions—urt caria, angioneurotic edema, anaphylaxis. Teeth—dental staining (ye low-brown) in children of mothers given this drug during the latter ha of pregnancy, and in children given the drug during the neonatal per od, infancy and early childhood. Enamel hypoplasia has been seen i a few children. If adverse reaction or idiosyncrasy occurs, discontinu medication and institute appropriate therapy. Demethylchlortetra cycline may form a stable calcium complex in any bone-forming tissu with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Shoul be given 1 hour before or 2 hours after meals, since absorption i impaired by the concomitant administration of high calcium conten drugs, foods and some dairy products. Treatment of streptococc infections should continue for 10 days, even though symptoms hav subsided.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Capsules: 150 mg; **Tablets:** film coated, 30 mg, 150 mg and 75 mg of demethylchlortetracycline HCl.

heavenly relief
for unearthly cough

Benylin®
EXPECTORANT

Each fluidounce contains: 80 mg. Benadryl® (diphenhydramine hydrochloride, Parke-Davis); 12 grains ammonium chloride; 5 grains sodium citrate; 2 grains chloroform; 1/10 grain menthol; and 5% alcohol.

An antitussive and expectorant for control of coughs due to colds or of allergic origin, BENYLIN EXPECTORANT is the leading cough preparation of its kind. BENYLIN EXPECTORANT tends to inhibit cough reflex... soothes irritated throat membranes. And its not-too-sweet, pleasant raspberry flavor makes BENYLIN EXPECTORANT easy to take.

PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this preparation. Hypnotics, sedatives, or tranquilizers if used with BENYLIN EXPECTORANT should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENYLIN EXPECTORANT.

ADVERSE REACTIONS: Side reactions may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, and blurring of vision have been reported. Allergic reactions may occur.

PACKAGING: Bottles of 4 oz., 16 oz., and 1 gal.

ARTHUR E. COCCO, MD
Journal Representative

Baltimore City Medical Society

MEETING NOTES

Nine of the members of the Board of Directors of the Baltimore City Medical Society met at 1211 Cathedral Street, December 3, 1968, at 4:30 PM. The meeting was called to order by D. Frank Kaltreider, MD. The minutes of the November 12th meeting were read and approved by the Board. Mrs. Karl Mech, President of the Women's Auxiliary of the Baltimore City Medical Society, was asked to appear before the Board in response to a letter sent from the Women's Auxiliary to the Baltimore City Medical Society requesting economic assistance. Mrs. Mech presented the problems confronting the Auxiliary with regard to operational expense. During the next fiscal year, beginning May, 1969, it is anticipated by the Auxiliary that it will be operating at approximately a one-thousand-dollar deficit. The budgetary requirements and income of the Auxiliary were presented in detail and the obvious economic deficit was discussed. The Board of Directors unanimously agreed that the ladies of the Women's Auxiliary are doing excellent, worthwhile, and constructive work, and the Board sympathized with their dilemma. After some consideration, it was decided that the incoming President, Raymond C. V. Robinson, MD, would select a committee to study the problem confronting the Women's Auxiliary and to make appropriate recommendations to the Board of Directors.

The next item on the agenda was the selection of nominees for the various appointments to be made from the Baltimore City Medical Society to The Medical and Chirurgical Faculty of the State of Maryland. These recommendations were as follows:

1) Donald W. Mintzer, MD, was nominated for consideration by the President-elect to The Professional Medical Services Committee as representative from the Baltimore City District.
2) No nominee was named from the Baltimore City Society to be considered for the Community Service Award to be presented at the annual meeting in 1969.
3) Howard Moses, MD, was nominated as representative from the Baltimore City Medical Society to serve on the Faculty's Legislative Committee during the 1969 General Assembly in Annapolis.
4) John N. Classen, MD, and Raymond C. V. Robinson, MD, were nominated as representatives to serve as liaison officers to the local news media during 1969.
5) John M. Dennis, MD, was nominated as a practicing physician nominee for possible inclusion in a list to be submitted to the Governor. From this list the Governor will select two physicians to serve on the Commission on Medical Discipline.

The next item on the agenda, presented to the Board of Directors, was a request for endorsement of a radio program entitled "Doctors' House Call." This program is commercially sponsored by the Giant Pharmacies, a Division of Giant Foods, Inc., and is presented in cooperation with the American Medical Association. The Board of Directors decided that, although the program agenda sounded worthwhile, they felt they could not support a private industrial-sponsored program.

A request from William Sawyer, MD, that his dues for 1969 be waived because of illness was unanimously granted by the Board.

Next was the presentation of the proposed budget for 1969 of the Baltimore City Medical Society. This report was submited by Emmanuel A. Schiminek, MD, Treasurer of the Baltimore City Medical Society.

Under new business, the Board of Directors agreed to submit a donation of $100 to the Student American Medical Association in accordance with the past practice of the Society.

Correspondence to the Board of Directors from Chief Martin McMahon of the Baltimore City Fire Department explained the present standardization of procedure concerning ambulance service in the city of Baltimore. Details of this standardization of operation will be sent to the members of the Society with the next mailing of correspondence.

This being the last meeting of the Board of Directors under the chairmanship of Dr. Kaltreider, the meeting was closed with his grateful acknowledgment to the Board of their cooperation during his term as President of Baltimore City Medical Society. The meeting was adjourned at 6:00 PM.

Book Reviews

INSTRUCTIONS FOR PATIENTS, H. Winter Griffith, MD; The W. B. Saunders Company, Philadelphia, Pa. 1968.

This collection of instruction sheets presents a simple method of putting into the patient's hands pertinent material about his medical problems. These can be read and reread at a time and place of his choice. The sheets will not take the place of talking to the patient, but they may make it possible to talk with the patient just once.

This loose-leaf binder will make a welcome addition to any physician's office; as a carte blanche is given the physician for making copies on his own copying machine.

QUESTIONS AND ANSWERS ON CONTACT LENS PRACTICE, Jack Hartstein, MD, The C. V. Mosby Company, St. Louis, Mo. 1968.

This book is essentially a compilation of practical information in contact lens fitting and is an outgrowth of material gathered in preparation for lectures and seminars given at various institutions. It provides the beginning practitioner with a detailed step by step procedure in the work-up and care of the contact lens patient, and provides essential information in a concise and readily available manner.

This book is a worthwhile addition to any medical library.

Average Salary for Hospital Personnel

The *New York Times* reports that the average salary for all hospital personnel was $5,140 in 1967. The AHA estimates there will be a 25% increase in average salary over the next two years, and that the number of full-time employees will increase by 5.1%. This means that by 1970 the annual hospital payroll for the voluntary hospitals alone will be very close to 9 billion dollars!

ACHROMYCIN® V
TETRACYCLINE

Contraindications: Hypersensitivity to tetracycline.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Nonsusceptible organisms may overgrow; treat superinfection appropriately. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Side Effects: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity reactions*—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

Modular Room to Provide

A room-within-a-room, specifically designed to provide a germ-free environment for patients with cancer during intensive anti-tumor therapy, is being developed for the National Cancer Institute by Litton Industries' Applied Science Division in Minneapolis, Minnesota.

Technically called a laminar flow patient isolator, the unit will be of modular design to fit into almost any hospital room presently accommodating two or more beds.

In a day's time a standard two-bed hospital room can be turned into a single-bed isolator care unit.

A $196,000 developmental contract was awarded to the Division late in June 1968 by the National Cancer Institute, a component of the National Institutes of Health (NIH), Bethesda, Maryland. NIH is an agency of the U. S. Department of Health, Education and Welfare (HEW). The program is under the direction of William Z. Penland who is project officer for the National Cancer Institute and Dr. Seymour Perry, Associate Scientific Director for Clinical Trials, NCI. The first units will undergo clinical testing in the Chemotherapy Area of the National Cancer Institute beginning in June 1969.

The germ-free environment created within the room will not only make possible more intensive treatment of patients with cancer, but it will also be suited for treatment of individuals with extensive burns; patients who have received heart, kidney or other transplants; and still other patients who are at high risk to infection. The sterile environment provided by these units would be vital to their well-being.

BALTIMORE, MD. 21214

Germ-Free Environment

The room will also have an inherent capability for containing micro-organisms, if so desired, and thus could be used to isolate patients with communicable diseases.

Key to the germ-free environment is the laminar flow design in which air passes through the room in a straight line and in a single direction. Thus, the air in front of the patient at any given moment is continuously clean and on the move, although he is not aware of air in motion. All of the air in the room is completely filtered six times each minute, or once every ten seconds.

Studies indicate that the laminar flow design can reduce the number of airborne organisms from 4,000 per 1,000 cubic feet of air to one per 1,000 cubic feet of air.

The laminar flow method is less confining and should enable the patients to remain under intensive care for a longer time, even for months if necessary.

Basic to the room is a bank of high efficiency particle arrestors (HEPA) filters, forming one of the walls. Structures for other walls are being evaluated—some include windows, others are designed for pass-through and storage. Wall modules will be of various sizes, with standard fittings to facilitate adapting them to hospital rooms. Also in the design evaluation stage is furniture for use within the room. It must be functional as well as psychologically acceptable, and must not disrupt the flow of air through the room.

The filter unit is designed to meet Air Force specifications, and will operate at 99.97% down to 0.3 micron efficiencies—a range that includes the trapping of bacterial particles.

K. Merrill Sumey, Resident Manager

A high index of suspicion... E. coli

How high is the "index of suspicion" for *E. coli* in urinary tract infections?

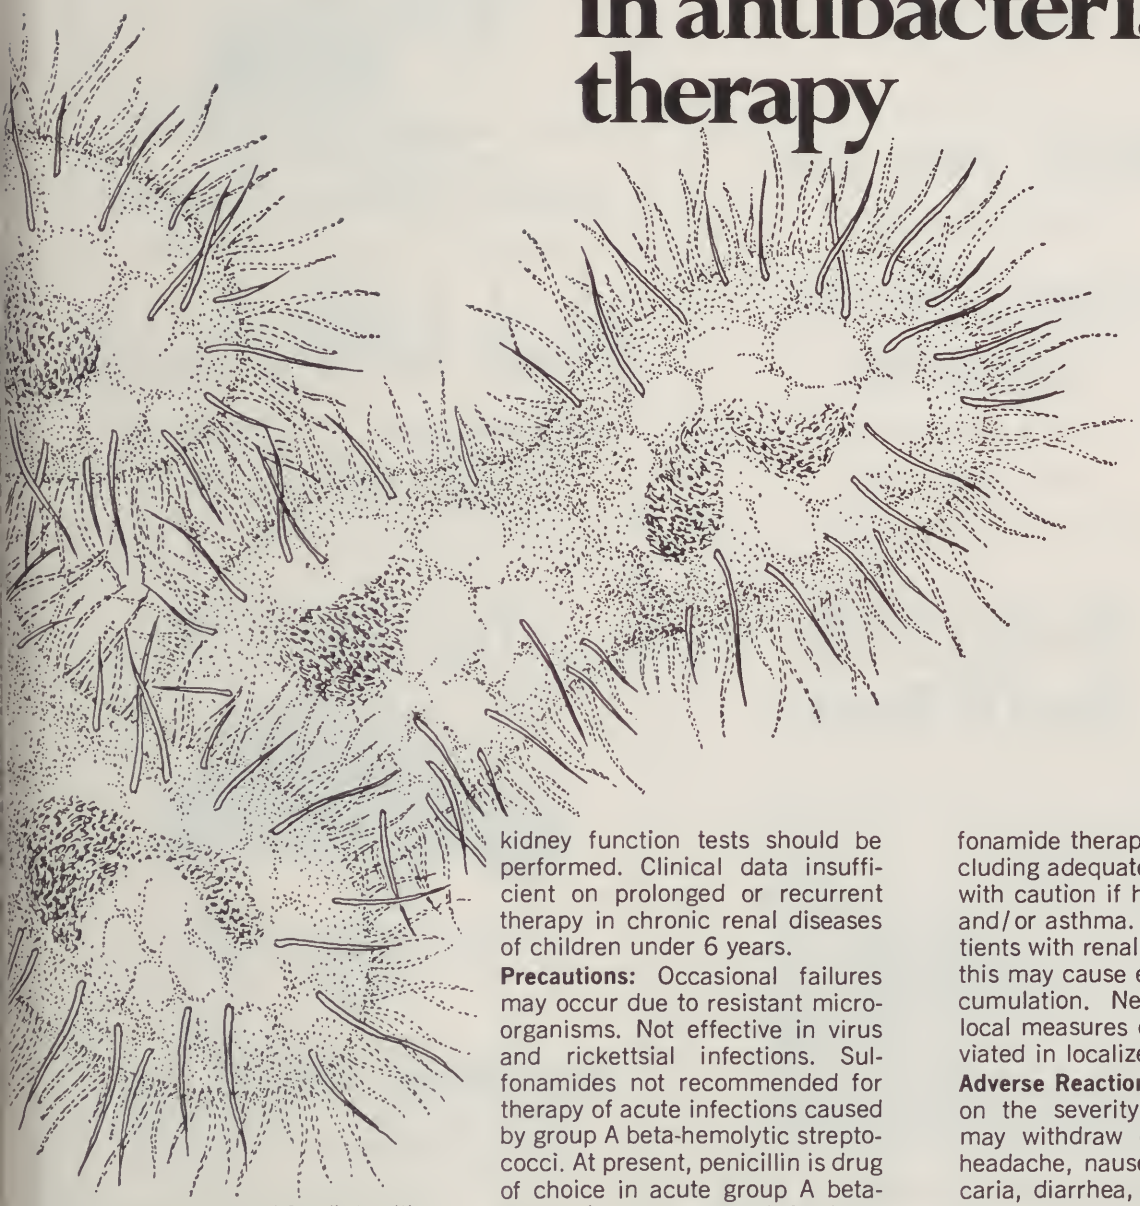
Recently it has been estimated that about 86 per cent of positive cultures in first attacks of urinary tract infection are *E. coli*.[1] It has also been noted that "The coliform group, especially *E. coli*, accounts for approximately 90 per cent of initial infections...."[2]

Consider wide-spectrum Gantanol® (sulfamethoxazole) for its high "index of confidence"—its proven effectiveness against *E. coli* and other sensitive gram-negative and gram-positive organisms. Therapeutic levels of Gantanol in blood and urine are achieved within 2 hours after a 2-Gm starting dose, with ready diffusion into interstitial fluids. Responsive infections generally clear within 5 to 7 days, with relief of symptoms usually seen within 24-48 hours.

Gantanol also earns its high "index of confidence" because Gantanol therapy is relatively free from complications, including the problem of bacterial resistance or superinfection.

Convenient, economical dosage schedule: *b.i.d.*

References: 1. Vernier, R. L., in Patient Care Feature: *Patient Care, 1*:20 (Feb.) 1967. **2.** Beeson, P. B.: "The Infectious Diseases," in Beeson, P. B., and McDermott, W. (eds.): *Cecil-Loeb Textbook of Medicine,* ed. 12, Philadelphia, W. B. Saunders Company, 1967, p. 230.



Before prescribing, please consult complete product information, a summary of which follows:

Indications: Acute and chronic urinary tract, respiratory and soft tissue infections due to susceptible microorganisms; prophylactically following diagnostic instrumental procedures on genitourinary tract.

Contraindicated in sulfonamide-sensitive patients, pregnant females at term, premature infants, or newborn infants during first 3 months of life.

Warnings: Use only after critical appraisal in patients with liver or renal damage, urinary obstruction or blood dyscrasias. Deaths reported from hypersensitivity reactions, Stevens-Johnson syndrome, agranulocytosis, aplastic anemia and other blood dyscrasias. In closely intermittent or prolonged therapy, blood counts and liver and

For a high index of confidence... Gantanol® (sulfamethoxazole) in antibacterial therapy

Artist's rendition of E. coli. As with most strains of E. coli, these have flagella and are motile.

kidney function tests should be performed. Clinical data insufficient on prolonged or recurrent therapy in chronic renal diseases of children under 6 years.

Precautions: Occasional failures may occur due to resistant microorganisms. Not effective in virus and rickettsial infections. Sulfonamides not recommended for therapy of acute infections caused by group A beta-hemolytic streptococci. At present, penicillin is drug of choice in acute group A beta-hemolytic streptococcal infections; although Gantanol has produced favorable bacteriologic conversion rates in this infection, data insufficient on long-term follow-up studies as to its effect on sequelae of rheumatic fever or acute glomerulonephritis. If other treatment cannot be used and Gantanol is employed in such infections, *important that therapy be continued in usual recommended dosage for at least 10 days*. Observe usual sulfonamide therapy precautions, including adequate fluid intake. Use with caution if history of allergies and/or asthma. Follow closely patients with renal impairment since this may cause excessive drug accumulation. Need for indicated local measures or surgery not obviated in localized infections.

Adverse Reactions: Depending upon the severity of the reaction, may withdraw drug in event of headache, nausea, vomiting, urticaria, diarrhea, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, Stevens-Johnson syndrome, skin rash, injection of the conjunctiva and sclera, petechiae, purpura, hematuria and crystalluria.

AMA Concern About Physician Supply Dates Back 50 Years

POLICY: A newspaper reporter asked the president of a state medical society why the American Medical Association had ignored the growing shortage of physicians until a year ago. The prevalence of this notion is hard to understand. The fact is that the AMA's concern with the problem of maintaining an adequate supply of physicians for the health needs of the nation can be traced back for at least half a century. As long ago as 1919, for example, the AMA House of Delegates recognized an increasing demand for physicians and called for improvements in medical education to meet the demand.

Again in 1922, the House of Delegates urged expansion of medical schools, construction of new schools and increased financial support of medical education, noting that "the tendency of medical colleges to limit their enrollments is causing some anxiety lest well-qualified students will be unable to secure admission to acceptable medical colleges."

In 1951 the House of Delegates stated that the AMA "has no desire to limit the production of properly trained physicians to serve the American people. The policy of the Association is to assist and encourage any responsible group or institution endeavoring to create new facilities or expand existing facilities for the training of physicians. . . . The Association does not attempt to regulate the size of the national student body in medicine. The number of students admitted . . . is determined by . . . each school, in accordance with the school's educational philosophy and its own judgment of its educational resources."

Only once in the last 50 years has the AMA suggested that the medical profession was overcrowded. That was in 1933 in the midst of the Depression.

But for the last quarter of a century the policy of the AMA has been that more physicians were needed. This policy has been reflected in pronouncements by the House of Delegates and the

Council on Medical Education and in statements by AMA officers. Just ten years ago the AMA again was urging medical schools to expand enrollments and to relax geographical restrictions on admission of new students.

In the past two years, the shortage of physicians has become increasingly more critical because the demand for health services has risen faster than the increase in facilities and personnel. There are several reasons. The American people are more knowledgeable about medicine, its progress and its benefits. They request more services because they know their value. They also are increasingly more affluent and they are willing and able to spend more on their health. The phenomenal growth of health insurance, easing the financial burden of illness and injury, has influenced the increase in demand. The U. S. population is rising and demand rises with it. A multitude of federal health programs have suddenly poured billions of dollars into an already overstrained health care system, increasing the demand and compounding the manpower problem. The number of physicians in government service has also contributed to the problem. More than 26,000 physicians, exceeding the total number of physicians taking care of patients in 23 of our states, are now in government service.

The charge that the AMA has ignored the problem is wholly unwarranted. The long-standing policy position that more physicians are needed has been translated into positive programs.

ACTIVITY: Seventeen years ago, the AMA recognized that many more medical schools would be needed quickly and began urging Congress to enact a program of federal grants for medical school construction and expansion. A dozen years elapsed, however, before the legislation was enacted. More recently, the AMA has endorsed the use of federal funds for aid in medical school operations.

Seeking to increase the supply of physicians, the AMA has also:

1. Conducted an extensive, continuing, nationwide careers program to attract more young men and women into careers in medicine or in allied health professions or occupations.
2. Inaugurated a loan guarantee program in 1962 to help students, interns and residents finance their education and training.

3. Called for creation of a national commission to properly balance government requirements for physicians against the needs of the public.
4. Participated in the planning and development of the 16 new medical schools which have been built since 1947 and the 10 others that will open by 1971.
5. Appointed a Committee on Health Manpower to study the entire problem of allocation of health resources and to develop constructive, workable solutions.
6. Recently joined with the Association of American Medical Colleges in an urgent program to increase enrollments in the nation's medical schools. The objective is expansion of enrollments to a level permitting all qualified applicants to be admitted.

In addition, the nation's physicians in the last 15 years have contributed almost $68,000,000 to U. S. medical schools, either directly or through the AMA Education and Research Foundation.

DIARRHEA

TROCINATE®

BRAND THIPHENAMIL HCl

The first 400 mg. Trocinate tablet usually relieves discomfort so promptly that Diarrhea ceases to be a bother

Trocinate has no known therapeutic value other than relaxing smooth muscle by direct action when coming in contact with the spastic muscle cell. Trocinate has none of the troublesome side-effects of anticholinergic drugs. Trocinate relieves the discomfort of diarrhea by decreasing both peristalsis and muscle tone. Trocinate is metabolized by the body and eliminated in the urine as harmless degradation products. Normal intestinal function is resumed.

The action of Trocinate is prompt, making the spacing of dosage easy. Often one or two 400 mg. tablets are sufficient to control diarrhea. The recommended dosage in spasm of the G. I. and G. U. tract is 400 mg. q. 4 h. A prescription of twelve (12) 400 mg. tablets will, in most cases, allow the patient to have a few to keep in reserve.

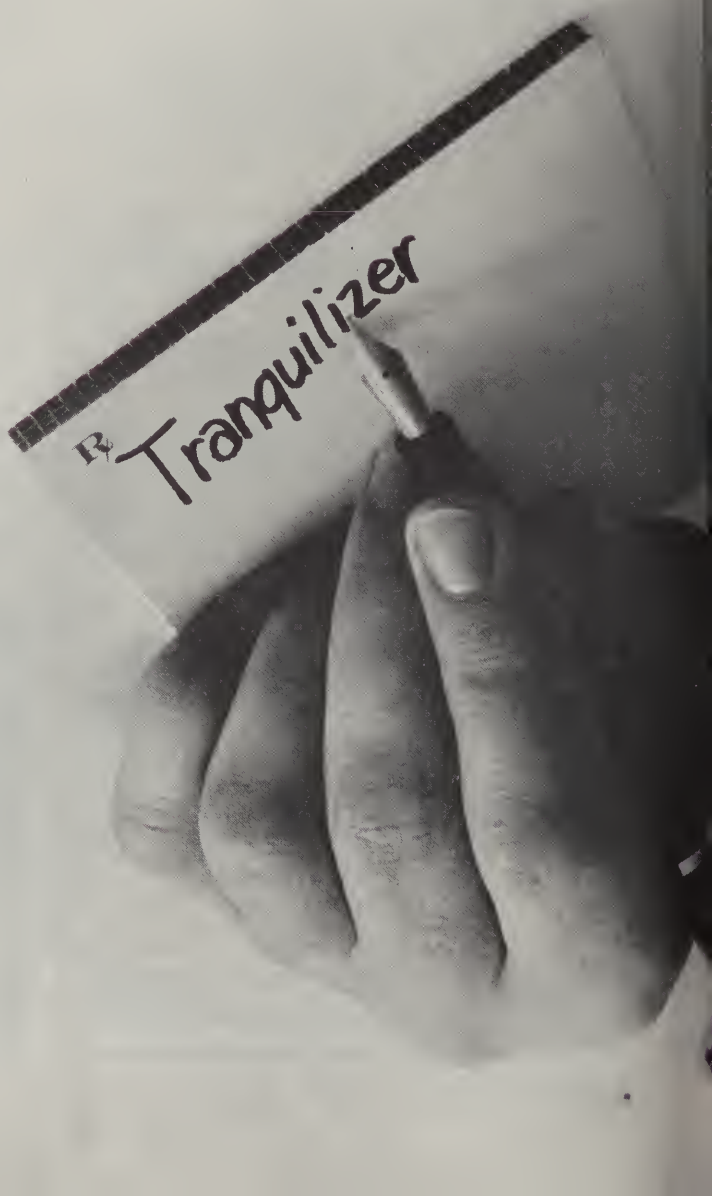
TROCINATE®



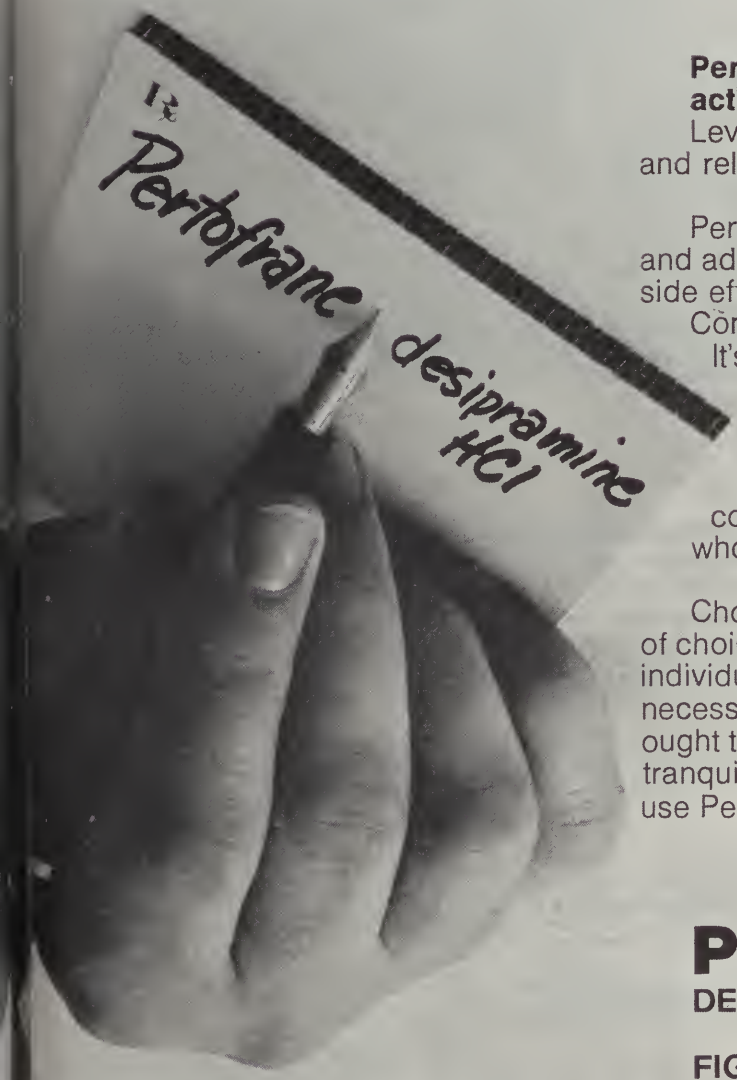
BRAND THIPHENAMIL HCl

DIARRHEA

Pertofrane®, desipramine hydrochloride
Indications: For relief of depression.
Contraindications: Do not use drugs of the M.A.O.I. class with Pertofrane. Hyperpyretic crises or severe convulsive seizures may occur; potentiation of adverse effects can be serious or even fatal. When substituting this drug in patients receiving an M.A.O.I., allow an interval of at least 7 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed.
Warning: Activation of psychosis may occasionally be observed in schizophrenic patients. Do not use in patients under 12 years old, and do not use in women who are or may become pregnant unless the clinical situation warrants the potential risk.
Precautions: Careful supervision and protective measures for potentially suicidal patients are necessary. Discontinuation of therapy or adjunctive use of a sedative or tranquilizer may be necessary in the presence of increased anxiety or agitation, hypomania or manic excitement. However, phenothiazines may aggravate the condition. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Carefully observe patients with increased intraocular pressure. Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications. Cardiovascular complications (myocardial infarction and arrhythmias) are potential risks since they have occasionally occurred with imipramine, the parent compound. Desipramine may block the pharmacologic activity of guanethidine and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery in patients on desipramine therapy.
Before prescribing the drug, the physician should be thoroughly familiar with prescribing information, with the literature, with all adverse reactions, with the diagnosis and management of depression, and with the relative merits of all measures for

You decide who needs how much

PRESCRIPT



treating the condition.
Adverse Reactions: Dry mouth, constipation, disturbed visual accommodation, anorexia, perspiration, insomnia, drowsiness, dizziness, headache, nausea, epigastric distress, and skin rash (including photosensitization) may appear. Since orthostatic hypotension has occurred, carefully observe patients requiring concomitant vasodilating therapy, particularly during the initial phases. Other adverse reactions include tachycardia, changes in EEG patterns, tremor, falling, mild extrapyramidal activity, neuromuscular incoordination, epileptiform seizures. A confusional state (with such symptoms as hallucinations and disorientation) occurs occasionally and may require reduced dosage or discontinuance of therapy. Rarely, transient eosinophilia, slight elevation in transaminase levels, transient jaundice, or liver damage have occurred. If abnormalities occur in liver function tests, discontinue drug and investigate. Occasional hormonal effects, particularly decreased libido or impotence and instances of gynecomastia, galactorrhea and female breast enlargement have been observed. Urinary frequency or retention may occur. The drug should be discontinued if agranulocytosis, bone marrow depression, jaundice, thrombocytopenia, or purpura occur.
Dosage: 25 to 50 mg. t.i.d. The maximum daily dose is 200 mg. Continue maintenance dosage for at least 2 months after obtaining satisfactory response. Generally, elderly and adolescent patients should be given low doses.
Availability: Pink capsules of 25 mg. in bottles of 100 and 1000.

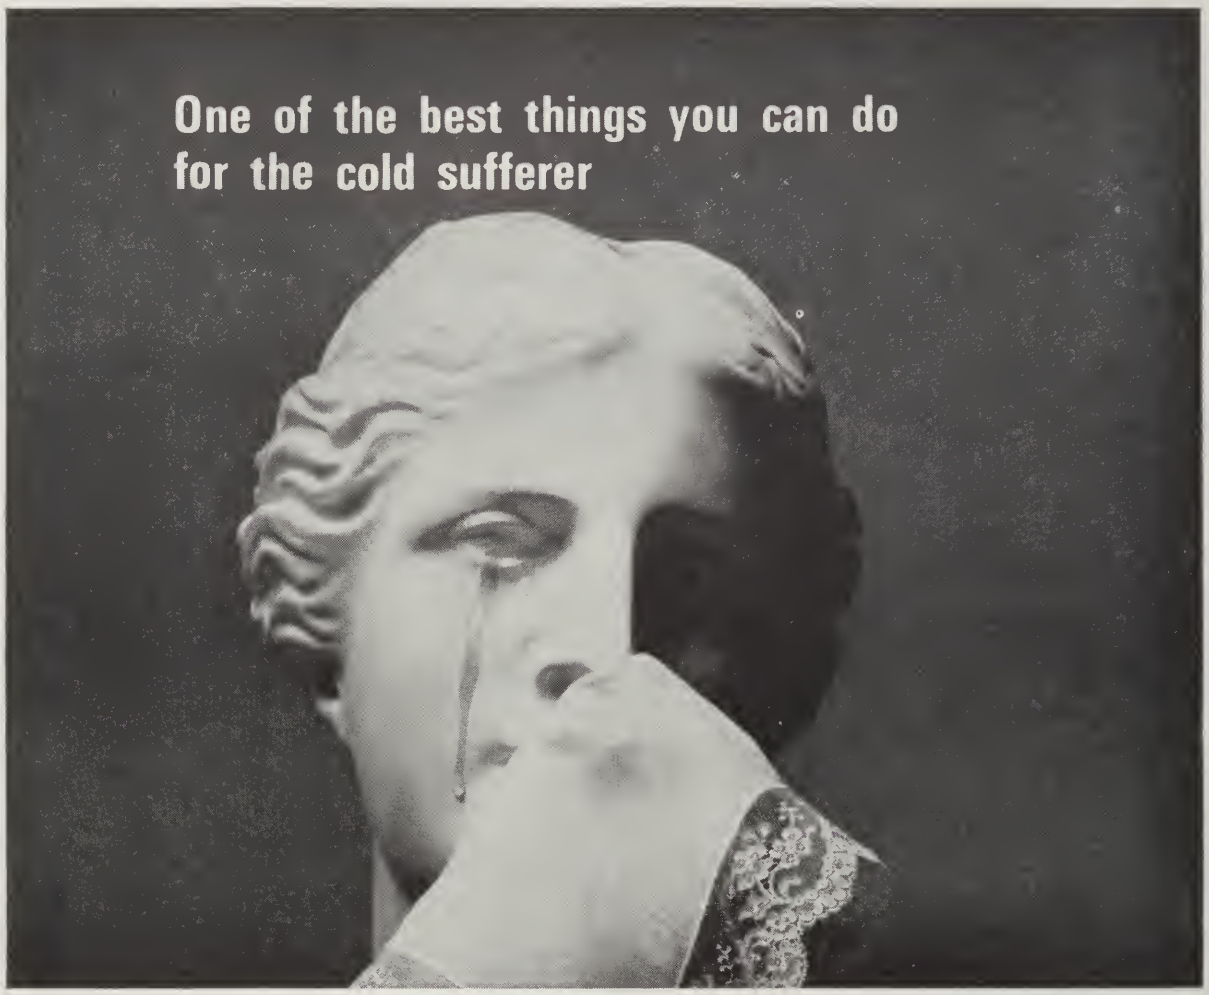
Geigy Chemical Corporation
Ardsley, New York 10502

antidepressant and how much tranquilizer—

ON POWER

Pertofrane can give rapid antidepressant action often within 3 to 5 days.
Levels of psychomotor activity, patient outlook and related somatic complaints may improve.

Pertofrane is well tolerated by most patients and adverse reactions are usually mild. A few serious side effects have been reported infrequently. Consult full prescribing information before using. It's summarized above.



Anxious Depressives...
May require adjunctive use of tranquilizers; but they don't always fit ready-made drug combinations. Isn't it better for *you* to decide who needs how much of which drugs?

Choose Pertofrane and pick your tranquilizer of choice. With this "combination", control the individual drug dosage adjustments that may be necessary for proper therapy. Isn't that the way it ought to be? Please remember, phenothiazine tranquilizers may aggravate depression, and never use Pertofrane with an MAO inhibitor.

PERTOFRANE®
DESIPRAMINE HYDROCHLORIDE

Geigy

FIGHTS DEPRESSION

Ornade®

Prompt relief from nasal congestion and hypersecretion due to colds.

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.
Contraindications: Glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal or bladder neck obstruction.
Precautions: Use cautiously in the presence of hypertension, hyperthyroidism, coronary artery disease; warn vehicle or machine operators of possible drowsiness.
Usage in Pregnancy: Use in pregnancy, nursing mothers and women who might bear children only when potential benefits have been weighed against possible hazards.
Note: The iodine in isopropamide iodide may alter PBI test results and will suppress I^{131} uptake; discontinue 'Ornade' one week before these tests.
Adverse Reactions: Drowsiness; excessive dryness of nose, throat or mouth; nervousness; insomnia. Other known possible adverse reactions of the individual ingredients: nausea, vomiting, diarrhea, rash, dizziness, fatigue, tightness of chest, abdominal pain, irritability, tachycardia, headache, incoordination, tremor, difficulty in urination. Thrombocytopenia, leukopenia and convulsions have been reported.
Supplied: Bottles of 50 capsules.

One capsule q12h for round-the-clock relief

Ornade® Trademark Each capsule contains 8 mg. of Teldrin® (brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; 2.5 mg. of isopropamide, as the iodide.

Volunteer Physicians for Vietnam

Statement by President Johnson on the Arrival of the 500th Physician Volunteer in South Vietnam. August 12, 1968

Three years ago South Vietnam welcomed the first American physician to volunteer for service in a Vietnamese civilian hospital. He was Dr. Richard E. Perry of St. Petersburg, Fla. This program was designed to relieve the suffering of civilians in a country suffering from a severe shortage of medical manpower.

Today, the 500th physician volunteer arrives in South Vietnam as a member of the American Medical Association's Volunteer Physicians for Vietnam program. Dr. Philip A. Pritel of Vancouver, Wash., is one of seven American doctors arriving today at Saigon's Tan Son Nhut Airport almost on the third anniversary of Dr. Perry's arrival in 1965.

Volunteer Physicians for Vietnam is a response to a plea from the South Vietnamese Government and people for medical aid. Supported by funds from the U. S. Agency for International Development, it is administered by the American Medical Association.

Physician volunteers serve 2 months without pay in Vietnamese civilian hospitals.

Physician volunteers have come from 49 States, the District of Columbia, the Canal Zone, and seven overseas posts. Fourteen women have served. Twenty-five doctors have served two tours, and five have served three times in this program. Twelve volunteers have returned to Vietnam as long-term employees to support the U. S. Medical Mission. Two former volunteers are preparing to return to Vietnam as medical missionaries.

Recruitment continues as the need in Vietnam continues; 32 physicians are needed every 60 days to maintain the program at its current strength.

The unselfish example demonstrated by these doctors makes us all proud of our American heritage of aiding the oppressed.

We lease car,

not cars (plural). Car (singular). When a professional man like you wants just one car.

We do one-car-at-a-time leasing with plans particularly appropriate for the professional man. Plans designed to give you the same advantages as enjoyed by big companies that lease.

These advantages include: the new '69 you want as you want it, no capital tied down in a depreciating asset, no separate maintenance or insurance bills, convenient service without extra charge at thousands of "Happy Motoring"® stations throughout the United States, exact transportation costs records on a single monthly bill for tax accounting, no trade-in problems or losses.

Many physicians and surgeons are now leasing. With good reason. Ask your nurse or secretary to drop us a note, or call us, for a detailed booklet explaining the Humble Leasing Plan.

Dead for an Hour,

Animals that have been "dead" for an hour are being returned to life in the hyperbaric oxygen chamber in a remarkable series of experiments conducted by three medical students, Charles McCluggage, Terry Quinn, and George Brown, under the direction of R. Adams Cowley, MD.

The team worked under the direction of Mr. McCluggage, who began the project with Donald Rice the previous summer.

The new procedure combines cooling, or hypothermia, with high pressure oxygenation. If it can be perfected for use in man it may offer an alternative to the heart-lung machine, which is used in most open heart operations and the more recent heart transplants.

Mr. McCluggage explains that pumping blood through such foreign bodies as the plastic tubing of a heart-lung machine almost inevitably damages blood cells, particularly in small children. The objective was to explore the effects of stopping circulation completely for a one-hour period in order to eliminate the need for shunting blood outside the body.

According to older criteria, stoping heartbeat and arresting circulation for four minutes would have meant the animal's death. But modern criteria of death include consideration of the brain's activity, in addition to that of the heart and lungs. In these experiments, supplying oxygen to the animal's tissues in the high pressure chamber protected the brain and other vital organs from damage. When the heart started beating again "death" lost its finality and became reversible.

"Oxygen requirements are reduced by one-third in our experiments just by cooling the animal to 77° F.," Mr. McCluggage said. "Cooling alone permits us to stop the animal's heart for about 15 minutes without damage to the brain. In addition, before we stop the heart by electrical shock

Animals Revived

we administer pure oxygen through a respirator to saturate the tissues. With the chamber pressure increased to three atmospheres, we can deliver 18 times the normal amount of oxygen, and this protects the brain for almost an hour.

"Three atmospheres of pressure, incidentally, is equivalent in scuba diving to going down about 66 feet in salt water. We use scuba terminology in the chamber—each treatment is a "dive.' "

Although the value of high pressure oxygen treatment has been well demonstrated in such conditions as gas gangrene, there was little knowledge about its use combined with hypothermia prior to these animal experiments.

"One sidelight of the research was to find how easily the heart can be started in the chamber," Mr. McCluggage said. "Cooling to 77° would ordinarily slow the heart to a stop, but not in the chamber. And most textbooks would say that when the heart is fibrillating at temperatures below 89° it cannot be defibrillated. In the chamber, at three atmospheres' pressure, we found it could be defibrillated easily much below 89°.

"The animals were anesthetized and monitored exactly as human patients would be. Each animal was given intensive care for about 24 hours after resuscitation. My classmates and I have spent many a night in Bressler lab caring for the animals. There was almost complete recovery after an hour's circulatory arrest."

The team looks forward to working in the 56-foot high pressure chamber in the new Shock Trauma Center, which will go into operation in January, 1970. And almost certainly, the knowledge they have gained in these experiments will prove even more useful to the advancement of medicine when more sophisticated equipment is available in the new chamber.

$14,000 in 1968 Equals $5000 in 1939

A family of four needs $14,000 a year to have the same purchasing power it had in 1939 according to the National Industrial Conference Board. In 1939, a $5000 a year man with 3 dependents had $4,941 to spend after taxes. Today he needs $14,282 to net the same because taxes chipped away $2,083 and inflation $7,258.

Med Students Aid Hard-Core Addicts

Twelve University of Maryland medical students, including ten members of the Student Health Organization, spent their summer days working with hard-core drug addicts in a rehabilitation program called Man Alive. This program offers treatment through the drug Methadone and through group therapy.

Methadone treatment has raised considerable controversy, since it too is habit forming, and many doctors feel that it merely substitutes dependence on one drug for another. Its advantage, however, is that it kills the craving for harder drugs and blocks their euphoric effects.

The Baltimore center at Mosher and Penn streets is one of three is the country that offers Methadone. There is another one on Belair Road and one in New York City.

The medical students, who had all received summer fellowships in psychiatry, led the therapy sesions. Robert Derbyshire, MD, supervised.

The idea for student participation in the project was sparked by SHO chairman Jerry Kay, a sophomore medical student. Mr. Kay feels that Methadone treatment and group therapy are much more successful than conventional treatment methods, ie, those offered by the federal government.

"We were all impressed with the intelligence and expressiveness of the addicts in the therapy sessions.

"I think that the medical community should be more aware of the narcotics problem. We often encounter hostility from doctors, and from law and federal officials who disapprove of Methadone."

Based on the success of the program on Mosher Street, SHO members are helping to set up therapy sessions at the Man Alive Center on Belair Road.

Information for Authors

MANUSCRIPTS: Manuscripts will be accepted for consideration for publication with the understanding that they are original, have never before been published, and are contributed solely to the Maryland State Medical Journal.

All manuscripts are acknowledged upon receipt and are followed up by notification of either acceptance or rejection. Rejected manuscripts are returned by regular mail. Accepted manuscripts become the property of the Journal and are not returned. The Journal is not responsible for loss of manuscripts through circumstances that are beyond its control.

Manuscripts should be addressed to: Editor, Maryland State Medical Journal, 1211 Cathedral St., Baltimore, Md. 21201.

SPECIFICATIONS: Manuscripts must be original typed copy, doublespaced throughout (Including text, case reports, legends, tables and references) with margins of at least 1½ inches. Pages should be numbered consecutively.

The manuscript should include the title (brief and concise), the full name of the author (or authors) with degrees, academic and professional titles, affiliations, and any institutional or other credits. Please include a complete address where the author may receive proofs of his article for his approval and corrections.

All manuscripts should be accompanied by a carbon or Xerox copy and the author should retain another copy for his records.

TABLES: Each table should be typed on a separate sheet of paper, be numbered, have a brief descriptive title, and its position in the text should be indicated.

Be sure that statistics are consistent in both tables and text.

REFERENCES: References should be limited to those citations noted in the text, and kept to a minimum of 18. (A complete review of the literature is rarely desirable.) The references must be typed, doublespaced, and are to be numbered consecutively as they appear in the text, with their positions in the text indicated. An alphabetized bibliography is used only when the listing is of books suggested for supplementary reading.

All references must be checked for absolute accuracy. Each journal reference must include author(s) and initials, complete title of article, name of publication, volume, first page of article, and date. Complete dates (month, day, and year) are to be included with all references that have appeared within the last three years. Include with book references name of author(s) and/or editor(s) with initials, title of book, edition, location, publisher, year, volume (if given), and page. If reference is to a chapter within a book, include the author of the chapter (if different from author of the book), and the title of the chapter, if any.

ILLUSTRATIONS: Authors are urged to use the services of professional illustrators and photographers when possible. Drawings and charts should always be done in black ink on white paper. Clear, glossy photographs, black on white, should be submitted and such illustrations numbered consecutively and their positions indicated in the text.

Magnifications will be modified in proportion to the amount of reduction necessary to fit the pages of the Journal. Please do not deface an illustration by writing on the front or the back, nor should it be taped or pasted to paper. The illustration may be pasted onto a piece of cardboard. Attached to the back of each illustration, chart or photograph should be the figure number, the author's name and the title of the article.

Legends for illustrations should be typewritten on a separate page with numbers corresponding to those on the photographs and drawings.

Recognizable photographs of patients are to be masked and should carry with them written permission for publication.

EDITORIAL RESPONSIBILITY: Manuscripts are subject to editorial modification and such revisions as are necessary to bring them into conformity with Journal style.

Statements made or opinions expressed by any contributor in any article or feature published in the Journal are the sole responsibility of the author.

PERMISSIONS: When material is reproduced from other sources, full credit must be given to both the author and publisher and written permission from these sources must be included when the material is submitted.

COPYRIGHT: Material that is published in the Maryland State Medical Journal is protected by copyright and may not be reproduced without the written permission of both the author and the Journal.

Symbols in a life of psychic tension

B.A.
cum laude

V.P.
at thirty-two

ECG
and complete examination normal
(persistent palpitations)

Valium®
(diazepam)

for reliable relief of psychic tension and associated somatic and depressive symptoms (including tension-induced insomnia)... usually well tolerated... 2-mg, 5-mg or 10-mg tablets *t.i.d.* and *h.s.*

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).
Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma.
Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms have occurred following abrupt discontinuance. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.
Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.
Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation, have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

OFFICIAL PUBLICATION OF THE MEDICAL AND CHIRURGICAL FACULTY OF THE STATE OF MARYLAND

VOLUME 18, NUMBER 3
MARCH 1969

BETHESDA MD 20014
9600 ROCKVILLE PIKE

In Honor Of Doctors' Day, March 30, 1969

"In the records of no other profession is there to be found so large a number of men who have combined intellectual pre-eminence with nobility of character."

SIR WILLIAM OSLER

Doctors' Day, honoring the men and women of the medical profession, is observed annually on March 30. This date commemorates one of the greatest milestones in medical history. For on this day, in 1842, Dr. Crawford W. Long first used ether anesthesia in surgery. In 1949, the red carnation was chosen the symbol for Doctors' Day.

In recognition of the doctors' contributions to the people and communities they serve, the Enoch Pratt Free Library is dedicating a window of the Central Library to Doctors' Day from March 25th to April 21st.

Honoring Doctors' Day, a contribution will be made by our Auxiliary to the American Medical Education and Research Foundation, to be divided equally between The Johns Hopkins and the University of Maryland Medical Schools.

Mrs. Karl F. Mech, *President*
Woman's Auxiliary to the
Baltimore City Medical Society

Mrs. John O. Sharrett, *Chairman*
Doctors' Day

LACTINEX®

TABLETS & GRANULES

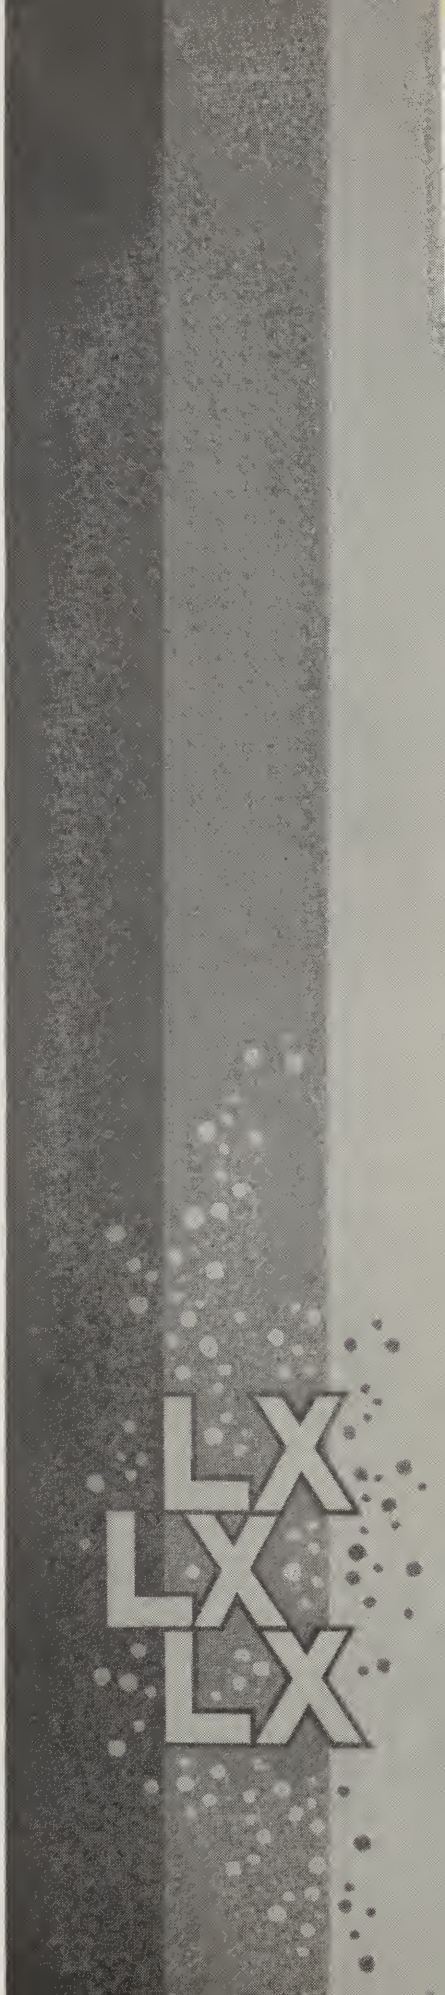
■ **to help restore and stabilize the intestinal flora**

■ **for fever blisters and canker sores of herpetic origin**

Lactinex contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

Lactinex has been shown to be useful in the treatment of gastrointestinal disturbances, and for relieving the painful oral lesions of fever blisters and canker sores of herpetic origin.[1,2,3,4,5,6,7,8]

No untoward side effects have been reported to date.



Literature on indications and dosage available on request.

HYNSON, WESTCOTT & DUNNING, INC.

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

b.i.d.

) guard susceptible patients against intestinal monilial over-owth during broad-spectrum therapy—the protection of ystatin is combined with demethylchlortetracycline in ECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN the broad-spectrum therapy that prevents monilial ergrowth.

fectiveness: Because its antibacterial component is DECLOMYCIN -methylchlortetracycline, DECLOSTATIN should be equally or more ective therapeutically than other tetracyclines in infections caused by racycline-sensitive organisms. The antifungal component, Nystatin, otects against superinfection by antibiotic-resistant fungal overgrowth articularly monilia) in the intestinal tract.

ntraindication: History of hypersensitivity to demethylchlortetracy-ne or nystatin.

rning: In renal impairment, usual doses may lead to excessive accum-tion and liver toxicity. Under such conditions, lower than usual doses indicated, and, if therapy is prolonged, serum level determinations y be advisable. A photodynamic reaction to natural or artificial sun-ht has been observed. Small amounts of drug and short exposure may oduce an exaggerated sunburn reaction which may range from ery-ma to severe skin manifestations. In a smaller proportion, photo-rgic reactions have been reported. Patients should avoid direct osure to sunlight and discontinue drug at the first evidence of skin comfort. Necessary subsequent courses of treatment with tetracy-es should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Demethylchlortetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

Lederle

LEDERLE LABORATORIES
A Division of American Cyanamid Company, Pearl River, New York

It's almost as if you were there to give an injection of penicillin

V-Cillin K®, Pediatric dependable oral penicillin therapy

Potassium Phenoxymethyl Penicillin

Description: V-Cillin K, the potassium salt of V-Cillin® (phenoxymethyl penicillin, Lilly), combines acid stability with immediate solubility and rapid absorption. Higher, more rapid serum levels are obtained than with equal oral doses of penicillin G.

Indications: Streptococcus, pneumococcus, and gonococcus infections; infections caused by sensitive strains of staphylococci; prophylaxis of streptococcus infections in patients with a history of rheumatic fever; and prevention of bacterial endocarditis after tonsillectomy and tooth extraction in patients with a history of rheumatic fever or congenital heart disease.

Contraindication: Penicillin hypersensitivity.

Warnings: In rare instances, penicillin may cause acute anaphylaxis which may prove fatal unless promptly controlled. This type of reaction appears more frequently in patients with a history of sensitivity reactions to penicillin or with bronchial asthma or other allergies. Resuscitative drugs should be readily available. These include epinephrine and pressor drugs (as well as oxygen for inhalation) for immediate allergic manifestations and antihistamines and corticosteroids for delayed effects.

Precautions: Use cautiously, if at all, in a patient with a strongly positive history of allergy.

In prolonged therapy with penicillin, and particularly with high parenteral dosage schedules, frequent evaluation of the renal and hematopoietic systems is recommended.

In suspected staphylococcus infections, proper laboratory studies (including sensitivity tests) should be performed.

The use of penicillin may be associated with the overgrowth of penicillin-insensitive organisms. In such cases, discontinue administration and take appropriate measures.

Adverse Reactions: Although serious allergic reactions are much less common with oral penicillin than with intramuscular forms, manifestations of penicillin allergy may occur.

Penicillin is a substance of low toxicity, but it possesses a significant index of sensitization. The following hypersensitivity reactions have been reported: skin rashes ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; and reactions resembling serum sickness, including chills, fever, edema, arthralgia, and prostration. Severe and often fatal anaphylaxis has occurred (see Warnings). Hemolytic anemia, leukopenia, thrombocytopenia, and nephropathy are rarely observed side-effects and are usually associated with high parenteral dosage.

Administration and Dosage: Usual dosage range, 125 mg. (200,000 units) three times a day to 500 mg. (800,000 units) every four hours. For infants, 50 mg. per Kg. per day divided into three doses.

See package literature for detailed dosage instructions for prophylaxis of streptococcus infections, surgery, gonorrhea, and severe infections.

How Supplied: Tablets V-Cillin K® (Potassium Phenoxymethyl Penicillin Tablets, U.S.P.), 125 mg. (200,000 units), 250 mg. (400,000 units), and 500 mg. (800,000 units).

V-Cillin K® (potassium phenoxymethyl penicillin, Lilly), Pediatric, for Oral Solution, 125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc. of solution (approximately one teaspoonful). [042567A]

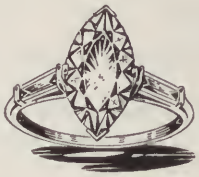
We recommend **CAMP**

SACRO-ILIAC SUPPORTS



Scientific block and tackle lacings cause the durable Camp material to firmly encircle the bony pelvis, in conservative treatment of sacro-iliac conditions. This basic Camp model also provides upper adjustment to balance the support or to ease spasm and pain, depending on the needs of the wearer. Effective for relief of effects of disease and moderate low back injury.

ADOPTION PROCEDURES

The Faculty office has been contacted in connection with activities on the part of some physicians who have become involved in adoption procedures. Several years ago, legislation was approved that prohibits any individual physician becoming involved in such activities. This law, however, does not apply to Washington and Garrett Counties.

Physicians are urged to utilize the booklet published by the Faculty, "Laws, Rules and Regulations with which Physicians Must Comply." This handy reference pamphlet can avoid many embarrassing situations.

SHEEN AWARD

The American Medical Association has advised the Faculty office to submit the name or names of candidates for the Sheen Award which offers a cash gift of $10,000. Candidates must be American citizens and physicians.

The award was established to honor "An Outstanding American Physician," and is a memorial to Rodman E. Sheen, MD, who died from injuries suffered in a Roentgen Tube explosion.

LAST CALL FOR ANNUAL MEETING

This is the last call for hotel reservations for the Faculty's Annual Meeting. A block of rooms has been reserved at the Belvedere Hotel, where many of the annual meeting functions will take place.

In asking for reservations, please indicate you are attending the Faculty's annual session.

REFERENCE COMMITTEE HEARING

The Reference Committee hearing has been scheduled for:

THURSDAY, MARCH 20, at 8:00 P.M.

in the Faculty building.

Resolutions for consideration at that time include the following:

Resolution 1S/68 - Workmen's Compensation Cases being charged on the basis of "Usual, Customary and Reasonable Fees"; and suggesting a course of action in

REFERENCE COMMITTEE HEARING (cont'd)

this regard.
(Action postponed until the Annual Meeting, 1969)

Resolution 1A/69 - Formation of a Standing Committee to Formulate Model Group Hospital and Medical Insurance Master Policies; and Make its Services Available to Interested Persons; and Urge the AMA Establish a Similar Committee.
(Introduced by Prince George's County Medical Society)

Resolution 2A/69 - Directing that Local Component Medical Societies Establish Policies on a Local Level for Yellow Page Telephone Directory Listings.
(Introduced by Washington County Medical Society)

Resolution 3A/69 - Authentication of House Staff Examinations by Attending or Operating Physician Prior to Major Medical or Surgical Procedures being Performed.
(Introduced by William G. Esmond, MD, and 36 other members)

PERSONALITIES

Gubernatorial appointments include:

William B. Long, MD, Salisbury, named to an additional term on the Board of Regents of the University of Maryland.

J. Sheldon Eastland, MD, Baltimore, to the Medical Board for Occupational Diseases.

Jonas Rappeport, MD, Baltimore, to the Board of the Patuxent Institute.

AMA APPOINTMENTS

William J. Peeples, MD, Baltimore, appointed to the Interspecialty Committee of the AMA.

Paul Q. Peterson, MD, Silver Spring, named as an alternate representative of the AMA on the USPHS Commission on Emergency Medical Services.

THE BEST AIDE KNOWN

Featherlite
Contour-Shaped
Surgical Two-Way

SEAMLESS ELASTIC HOSIERY

Now! . . . a new concept in elastic hosiery achieves excellent cosmetic effect and provides the necessary therapeutic qualities of surgical weight. Using a patented inlay method to insure proper lateral support, fine gauge nylon-covered rubber thread is knitted with MAGILOFT (stretch nylon) yarn to produce a lightweight elastic two-way stretch stocking highly resistant to runs and snags.

For the FIRST time in this field, both STOCK and SPECIALS are available; thus you may offer your patients complete selection of elastic two-way stretch stockings with proper compression, regardless of size or shape.

The Contour-Shape, combined with a MAGILOFT SOFT TOP and knitted-in heel, has eliminated wrinkles at ankle and all tendency to slip down at the top.

The SUPPORT of surgical weight is retained with the advantages of light weight, and all the desirable features of fine gage hosiery.

Downtown Westminster at 6 East Main Street.

Dear Doctor, You made me what I am today — a whole lot slimmer!

TEPANIL —the right start in support of the weight-control program *you* recommend. It reduces the appetite. Doesn't kill it. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation. Because TEPANIL works on the appetite, not on the "nerves."

Contraindications: Contraindicoted concurrently with MAO inhibitors, in patients hypersensitive to diethylpropion hydrochlaride, and in emotionolly unstable patients knawn to be susceptible ta drug abuse.

Warning: Althaugh generally sofer than the omphetamines, use greot cautian when prescribing for potients with severe hypertension or severe cardiovascular diseose. Shauld not be used during the first trimester af pregnancy unless potential benefits autweigh potential risks.

Side Effects: While rarely causing theropy to be withdrawn, side effects moy accur occosionally; CNS effects (such as insomnia, nervousness, jitteriness), dryness af mouth, thirst, nausea, abdominal distress, canstipotian, headoche, ollergic respanse including urticario or other dermotitis; rarely assaciated with tachycardia, cordioc arrhythmio or ECG changes.

Convenience of two dosage forms: TEPANIL Ten-tab toblets: One 75 mg. tablet daily, swallowed whale, in midmorning (10 o.m.); TEPANIL: One 25 mg. toblet three times daily, one hour before meals. If desired, on additional tablet may be given in midevening to avercame night hunger.

Use in children under 12 years of age is not recommended.

THE NATIONAL DRUG COMPANY
DIVISION OF RICHARDSON-MERRELL INC.
PHILADELPHIA, PENNSYLVANIA 19144

Tepanil® Ten-tab®

(continuous release form)

(diethylpropion hydrochloride)

So he'll breathe easier:

relieve anxiety while you relieve pain.

Relief of pain is usually a major goal in traumatic conditions. But often of importance, too, is alleviation of anxiety and tension that may heighten patient discomfort.

Single-prescription, non-narcotic Equagesic may effectively relieve pain. *And* ease anxiety and tension.

TABLETS

Equagesic®

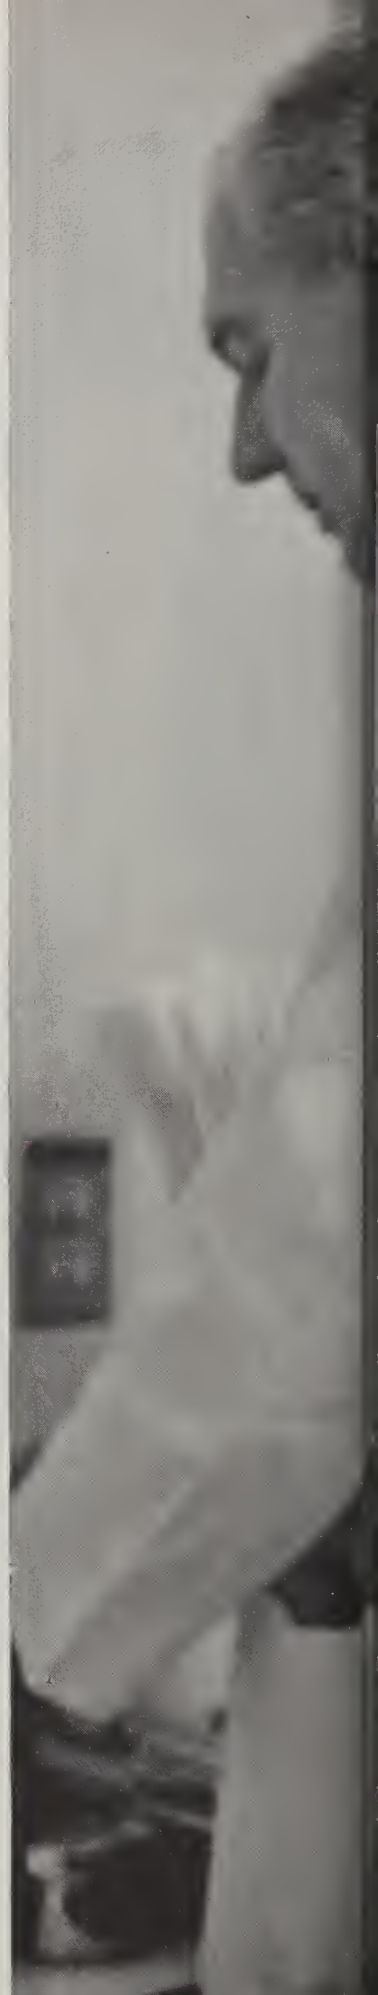
(meprobamate and ethoheptazine citrate with aspirin) Wyeth®

IN BRIEF.

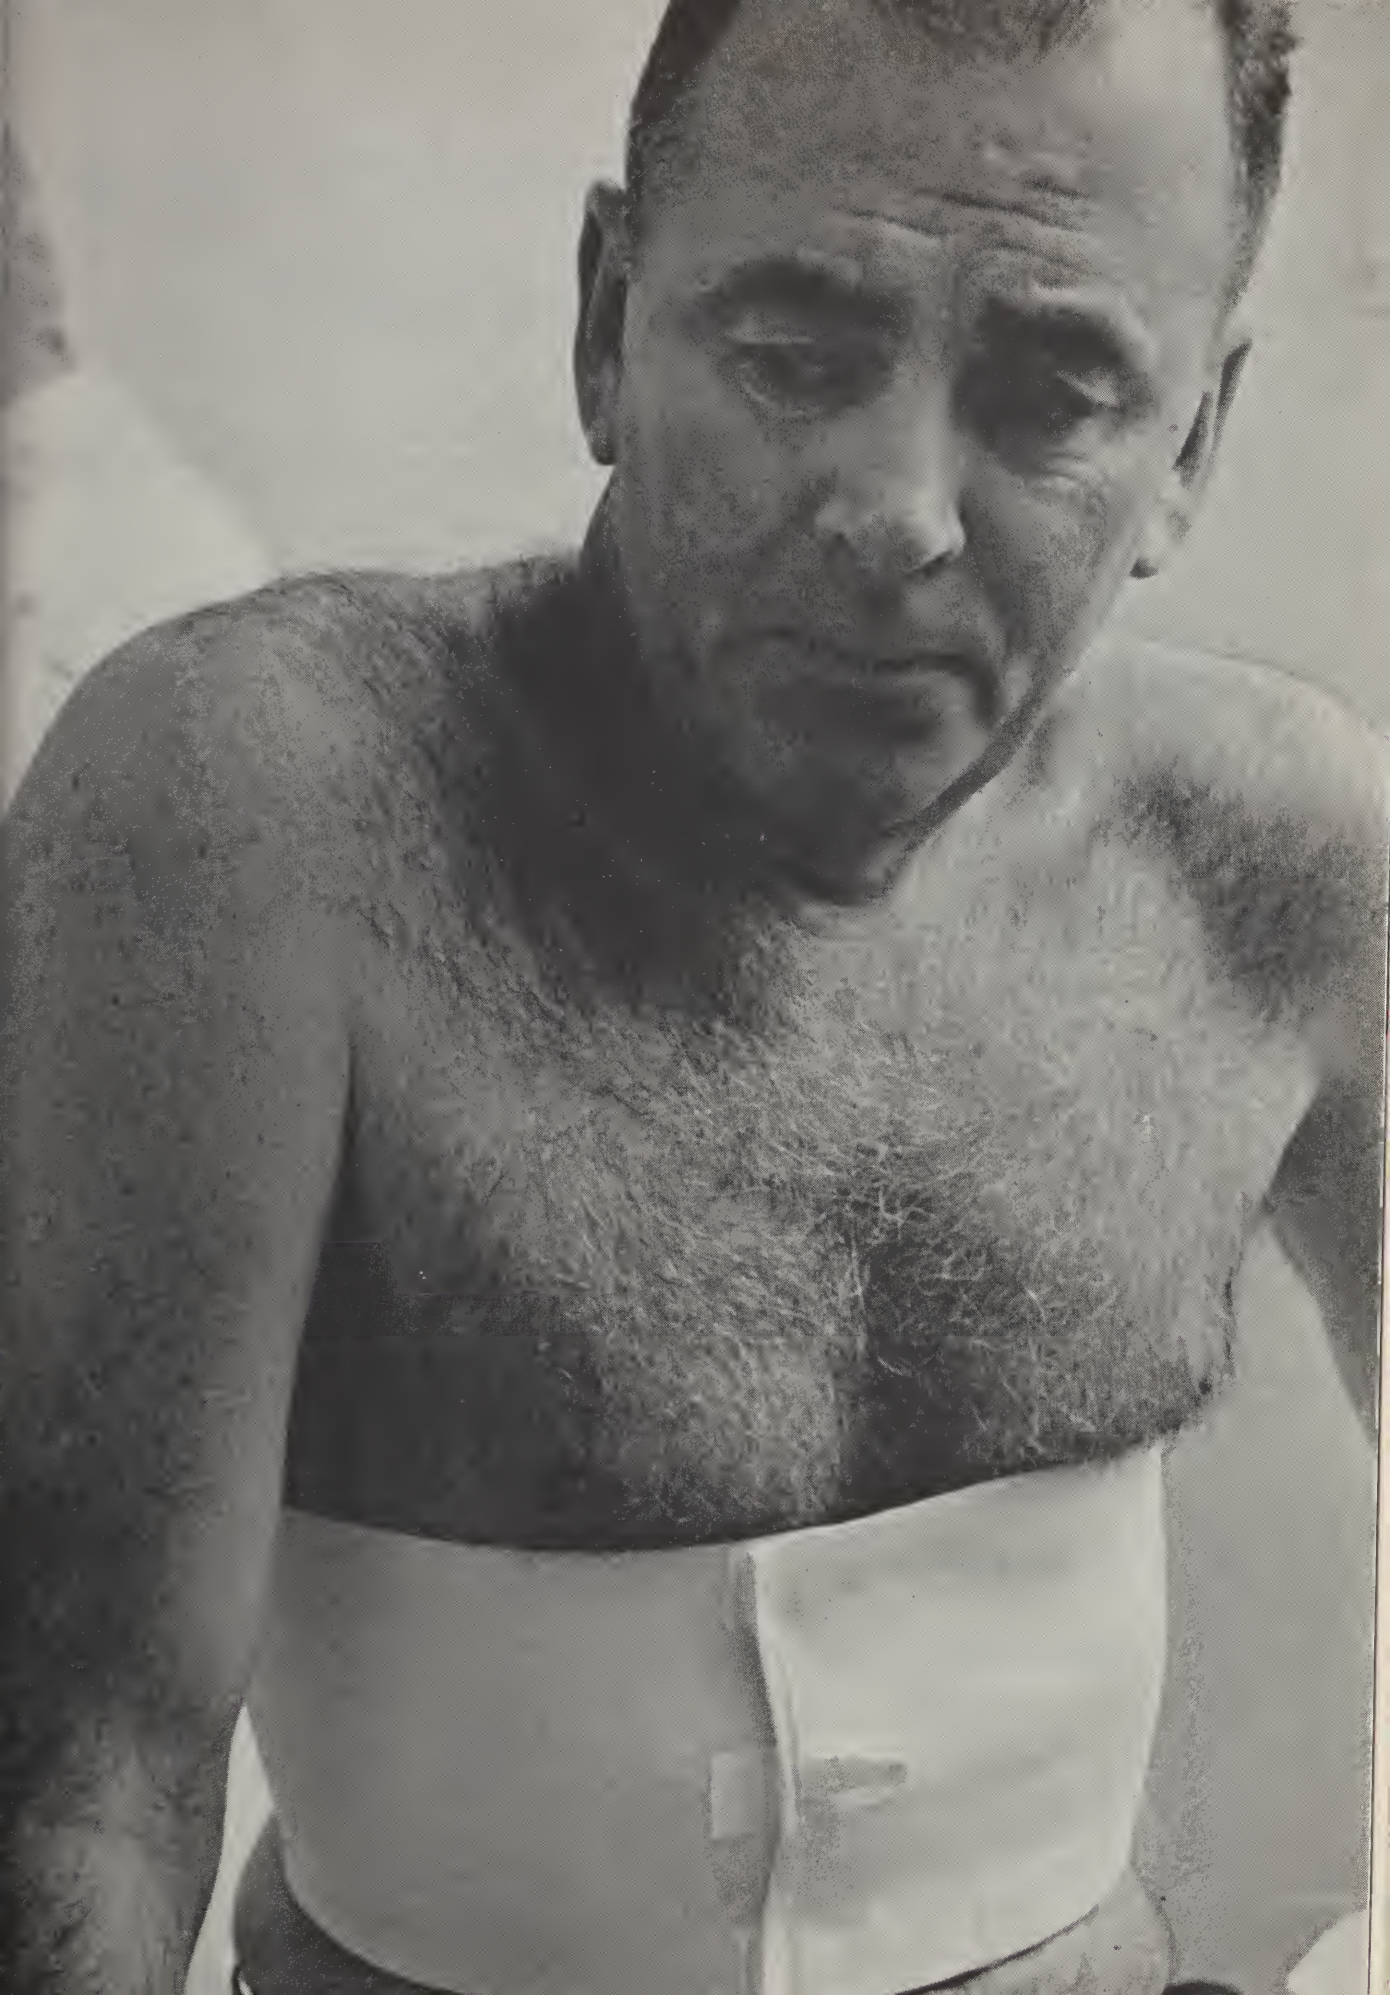
Contraindications: History of sensitivity or severe intolerance to aspirin, meprobamate or ethoheptazine citrate.

Warnings: USE IN PREGNANCY: Safety for use during pregnancy or lactation has not been established; therefore, it should be used in pregnant patients or women of child-bearing age only when the physician judges its use essential to the patient's welfare.

Precautions: Keep out of reach of children. Not recommended for patients 12 years old or less. Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use of meprobamate in susceptible persons—as alcoholics, ex-addicts, severe psychoneurotics—has resulted in dependence or habituation. Withdraw gradually after prolonged excessive dosage to avoid possibly severe withdrawal reactions including epileptiform seizures. Warn patients of possible reduced alcohol tolerance, with resultant slowed reactions and impaired judgment and coordination. If drowsiness, ataxia or visual disturbances (impairment of accommodation and visual acuity) occur, reduce dose. If symptoms persist, patients should not operate machinery or drive. After meprobamate overdose, prompt sleep, reduction of blood pressure, pulse and respiratory rates to basal levels, and hyperventilation are reported. Give cautiously and in small amounts to patients with suicidal tendencies. Treat attempted suicide (has resulted in coma, shock, vasomotor and respiratory collapse and anuria) with gastric lavage and appropriate symptomatic therapy (CNS stimulants and pressor amines as indicated). Two instances of accidental or intentional significant overdosage with ethoheptazine and aspirin have been reported. These were accompanied by CNS depression (drowsiness and lightheadedness) but resulted in uneventful recovery. On basis of pharmacologic data, CNS stimulation could be anticipated, with nausea, vomiting and salicylate intoxication (requires induced vomiting or gastric lavage, specific parenteral electrolyte therapy for ketoacidosis and dehydration, and observation for hypoprothrombinemic hemorrhage [usually requires whole blood transfusions]).



Adverse Reactions: Ethoheptazine and aspirin may cause nausea with or without vomiting and epigastric distress, in a small percentage of patients. Dizziness is rare at recommended dosage. Meprobamate may cause drowsiness, ataxia and rarely allergic or idiosyncratic reactions. These reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses. Such patients may have had no previous contact with meprobamate and may or may not have an allergic history. Mild reactions are characterized by urticarial or erythematous maculopapular rash. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. If allergic reaction occurs, discontinue meprobamate; do not reinstitute. Severe reactions, observed very rarely, include fever, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. These cases should be treated symptomatically including, when indicated, such medication as epinephrine, antihistamine and possibly hydrocortisone. A few cases of leukopenia, usually transient, have been reported on continuous use. Rarely, aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis, and hemolytic anemia have been reported, almost always in presence of known toxic agents.



Overdosage: See precautions section for management of overdosage.

Composition: 150 mg. meprobamate, 75 mg. ethoheptazine citrate and 250 mg. aspirin per tablet.

Wyeth Laboratories Philadelphia, Pa.

K. Merrill Sumey, Resident Manager

PRACTICAL PSYCHIATRY FOR THE INTERNIST, Douglas Goldman, MD, and George A. Ulett, MD; The C. V. Mosby Company, St. Louis, Mo. 1968.

The main purpose of this publication is to make the practitioner aware of his own emotional and psychologic functions and the likelihood that he will become involved in the therapeutic interchange with the patient. However, a reasonably smooth transition into the future practice of medicine will require some familiarity at a working level with psychological and emotional aspects of illness, particularly with practical therapy, which must involve interchange (psychotherapy) and application of chemical and physiologic knowledge (psychopharmacology). This volume does well in its presentation of this.

DIAGNOSIS OF SURGICAL DISEASE, Vols I, II, III, Richard T. Shackelford, MD; The W. B. Saunders Co., Philadelphia, 1968.

The author states ". . . I am convinced that most failures of surgical treatment are caused by errors in diagnosis, and that most errors in diagnosis are made because the correct diagnosis simply did not come to mind. . . . For this reason, many disorders which are non-surgical, or belong in the fields of surgical subspecialties, or require no treatment at all, are mentioned so as to remind attending surgeons of their existence."

Dr. Shackelford indicates that the subject matter in the volumes has been arranged according to the usual sequence of events that occur when a patient is first seen by a surgeon. Hence, the first two chapters are on the "time-worn, elementary" subjects of the history and physical examination, but the author's treatment of the rudiments is unique.

All three volumes are combined in a single, well-organized, well-presented bound book. It would be a worthwhile addition to any physician's library whether or not he is involved in surgery or a surgical subspecialty.

THE LANGUAGE OF THE TRANSFERENCE, David W. Shave, MD; Little, Brown & Co., Boston, 1968.

Dr. Shave's book is the result of a two-year study of recorded psychotherapy sessions. It is Vol. 5, No. 2 of the International Psychiatry Clinics series.

"The transference relationship is shown to be a highly dynamic, constantly shifting interaction between the patient and the therapist reflecting, in part, not only the past psychopathological interpersonal relationship of the patient but also the orientation and presentation of the many-faceted ambivalent feelings the patient has toward the different aspects of the therapist as perceived by the patient. . . . "

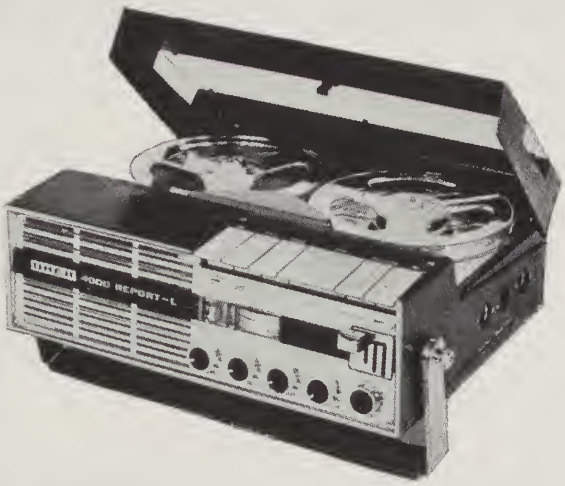
According to the author, a Maryland psychiatrist, "the purpose of the monograph is not to offer a new type of therapy, but to offer a fundamental theory of a patient's communicative behavior underlying any psychotherapeutic relationship and a recognition of an impressive ego function in working latent content into manifest content. It also offers a method of psychological research completely compatible with past and present analytical theory . . . the goal of the studies . . . is a better understanding of language in any psychotherapeutic endeavor."

WATER AND ELECTROLYTE METABOLISM AND ACID-BASE BALANCE, Edward Muntwyler, PhD; The C. V. Mosby Co., St. Louis, 1968.

This book provides a detailed and simplified treatment of various fundamental principles and examples of practical application in connection with water and electrolyte metabolism. It is an attempt to meet the requests of students for material on water and acid-base balance. It is a clear and concise work which merits a position in a reference library.

SYMPOSIUM ON SURGICAL AND MEDICAL MANAGEMENT OF CONGENITAL ANOMALIES OF THE EYE, from Transactions of the New Orleans Academy of Opthalmology; The C. V. Mosby Co., St. Louis, 1968.

The large attendance at this symposium, devoted to genetically oriented and associated conditions of the eye, prompted the publication of this copy of the transactions of this session. It is well worthwhile to include in any medical library.



THE NEW UHER 4000-L

Professional Portable Tape Recorder

a

martel

presentation

The UHER 4000-L combines features badly needed by the medical profession, found in no other portable recorder.

FOR LECTURES

Will record up to 8½ hours on one five-inch reel

QUALITY RECORDING AND PLAYBACK

Used by radio stations for interviews and "on the spot recordings"

LISTENING TO MEDICAL TAPES

Can be used in car, home, or office.

A few of the distinctive OPERATING FEATURES of the incomparable UHER 4000-L

Easy operation with brushed aluminum piano-key controls
Three-digit index counter with push-button reset
Fully transistorized and weighs less than 7 lbs.
Picture-window top for improved tape observation

Plus many other outstanding features

You've made it one of your specifics in acute otitis media

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

You've made it one of your specific in acute otitis media

DECLOMYCIN acts against many strains of H. influenzae, pneumococci and streptococci, the most common invaders. In otitis media, where it is difficult to isolate the causative organism, this coverage may be important. However, some strain may be resistant and other pathogens can be involved.

You've found the high serum levels of DECLOMYCIN important, too. Its prolonged actio permits convenient 300 mg b.i.d. or 150 mg q.i.d. administration.

When specimens are obtainable, your culture studies will indicate the usefulness of DECLOMYCIN.

Effectiveness: DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines in infections caused by organisms sensitive to the tetracyclines.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocoliti pruritus ani. Skin—maculopapular and erythematous rashes; a ra case of exfoliative dermatitis has been reported. Photosensitivit onycholysis and discoloration of the nails (rare). Kidney—rise in BU apparently dose-related. Transient increase in urinary output, som times accompanied by thirst (rare). Hypersensitivity reactions—urt caria, angioneurotic edema, anaphylaxis. Teeth—dental staining (ye low-brown) in children of mothers given this drug during the latter h of pregnancy, and in children given the drug during the neonatal pe od, infancy and early childhood. Enamel hypoplasia has been seen i a few children. If adverse reaction or idiosyncrasy occurs, discontinu medication and institute appropriate therapy. Demethylchlortetra cycline may form a stable calcium complex in any bone-forming tissu with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Shoul be given 1 hour before or 2 hours after meals, since absorption i impaired by the concomitant administration of high calcium conte drugs, foods and some dairy products. Treatment of streptococc infections should continue for 10 days, even though symptoms hav subsided.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Capsules: 150 mg; **Tablets:** film coated, 30 mg, 150 mg and 75 mg of demethylchlortetracycline HCl.

American Cyanamid Company, Pearl River, New York

Lederle

now she can cope...

thanks to

Butisol SODIUM®
(SODIUM BUTABARBITAL)

the "daytime sedative" for everyday situational stress

When stress is situational—environmental pressure, worry over illness—the treatment often calls for an anxiety-allaying agent which has a prompt and predictable calming action and is remarkably well tolerated. BUTISOL SODIUM (sodium butabarbital) meets this therapeutic need.

After 30 years of clinical use . . . still a first choice among many physicians for dependability, safety and economy in mild to moderate anxiety.

Contraindications: Porphyria or sensitivity to barbiturates.

Precautions: Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression.

Adverse Reactions: Drowsiness at daytime sedative dose levels, skin rashes, "hangover" and systemic disturbances are seldom seen.

Warning: May be habit forming.

Usual Adult Dosage: As a daytime sedative, 15 mg. (¼ gr.) to 30 mg. (½ gr.) t.i.d. or q.i.d.

Available for daytime sedation: Tablets, 15 mg. (¼ gr.), 30 mg. (½ gr.); Elixir, 30 mg. per 5 cc. (alcohol 7%).

BUTICAPS® [Capsules BUTISOL SODIUM (sodium butabarbital)] 15 mg. (¼ gr.), 30 mg. (½ gr.).

McNEIL

171st Annual Meeting

More prominent speakers * who will present papers during the Annual Meeting in April include Burtis E. Montgomery, MD, and Robert H. Johnson, Jr., MD.

At the annual Presidential Banquet on Thursday, April 10, **Burtis E. Montgomery, MD,** Chairman of the Board of Trustees of the American Medical Association, will speak on *New Horizons in Medicine.* This will be the Amos R. Koontz, MD, Memorial Fund Lecture. Dr. Montgomery will speak of some of the things the profession is looking forward to, some of the things that could happen, and what the future holds, particularly for the younger people in medicine.

Dr. Montgomery, of Harrisburg, Illinois, was elected to the American Medical Association's Board of Trustees in June 1966, and was named board chairman in June 1968. He has served as president of both the Illinois State Medical Society and the Southern Illinois Medical Association. Dr. Montgomery is a past member of the board of directors of the National Association of Blue Shield Plans and is at present a member of the board of directors of Blue Shield-Illinois Medical Service. He is a fellow of the International Academy of Medicine, the American Geriatric Society and the American College of Physicians; a member of the American Society of Internal Medicine; and a past member of the Medical Examining Board, Department of Registration and Education, State of Illinois.

A practicing internist, Dr. Montgomery interned at St. Luke's Hospital in Chicago, and did part of his postgraduate work at the Massachusetts General Hospital. He is the holder of cum laude honors from the College of Medicine of the University of Illinois, and in 1967 was named alumnus of the year by that university's Medical Alumni Association. On the lighter side, Dr. Montgomery enjoys two major hobbies—golf and playing the drums.

The I. Ridgeway Trimble Fund Lecture will be given at the Annual Meeting by **Robert H. Johnson, Jr., MD,** whose subject will be *Detection of Head and Neck Cancer.* Dr. Johnson was graduated from Duke University and received his MD degree at the University of Maryland School of Medicine, where he is currently assistant professor of surgery. He served a rotating internship and residency in surgery at the University of Maryland Hospital. In 1960, Dr. Johnson was a clinical associate at the Oak Ridge Institute of Nuclear Study; in 1962 he was a fellow at the MD Anderson Hospital and Tumor Institute in Houston; and from 1965 to 1968 he was senior investigator, surgery branch, National Cancer Institute, National Institutes of Health.

Dr. Johnson is a member of the Society of Head and Neck Surgeons, the Baltimore Academy of Surgery, and the University of Maryland Surgical Society. Included among his many publications are: Complications of Intra-cranial Facial Resection for tumors at the Para-nasal Sinuses; Examination of the Mouth; Surgery in the Role of Treatment of Advanced Oral Pharyngeal Cancer; and Infusion and Radiotherapy for the Treatment of Advanced Cancer of the Head and Neck.

* See the December, January and February Journals for capsule biographies of **Robert L. Evans, MD, Howard W. Jones, Jr., MD, Milton Helpern, MD, Joseph Lee Hollander, MD, Denton A. Cooley, MD,** and **George D. Zuidema, MD,** who also will be featured during the scientific sessions of Annual Meeting in April.

P.D.Q. SERVICE ESPECIALLY FOR DOCTORS *Professional, Dependable, Quick Auto Repairs. Our service department has instructions to give precedence to doctors in immediate, accurate electronic diagnosis and prompt, expert therapy on any make car to avoid unnecessary delay in your valuable service to the community.*

COMPONENT SOCIETIES

Baltimore County Medical Association

Theodore Patterson, MD, a general practitioner in the Dundalk area, has been elected president of the Baltimore County Medical Association. Dr. Patterson graduated from the University of Maryland School of Medicine in 1962 and interned at Sinai Hospital in Baltimore. He was assistant resident in medicine at the South Baltimore General Hospital. Dr. Patterson is a member of the American Medical Association, the Medical and Chirurgical Faculty of Maryland, chairman of the Human Relations Council of the Greater Dundalk area, a member of the Baltimore County Senior Citizens Council and a member of the Maryland Academy of General Practice.

Dr. Patterson

The new Vice President of the Association is Wilmer Gallager, Jr., MD, of Catonsville, and the Secretary-Treasurer is John N. Krager, MD, of Towson. The Delegates to the Medical and Chirurgical Faculty House of Delegates are Melvin Davis, MD, Edward Krieg, MD, Gordon Grau, MD, Martin Strobel, MD, Clarence McWilliams, MD, William McGrath, MD, and Charles Williams, MD.

The new address for the Association is 8523 Loch Raven Boulevard where a full-time executive secretary will be located.

Carroll County Medical Society

The Carroll County Medical Society met January 8, 1969 at Hoffman's Inn. Officers for the 1969 term are as follows: President, William R. O'Rourke, MD; President-Elect, John S. Harshey, MD; Secretary, Richard A. Jones, MD; Treasurer, Dean Griffin, MD; One Member-at-Large, Sherman Chang, MD, and Executive Secretary, Nancy B. Jones.

Mr. R. Poole and Mr. A. Weismantel outlined their newly available program for physical therapy at the Carroll County General Hospital.

Mr. Jack Sargeant spoke briefly of various matters of medical interest pending before the Legislature.

Our Society continues to be active in a number of community activities. The most current ones are the Farm Museum Project and the Family Doctor Program. At the Farm Museum Village, we will have a doctor's home and office combination of the 1850 era. Anyone knowing of furniture or equipment that could be used in such an exhibit is asked to contact the Carroll County Medical Society. The Family Doctor Program is broadcast over the local radio station three times weekly and covers topics that are of interest to the entire community.

PHILIP W. MERCER, MD
Journal Representative

Howard County Medical Society

The Howard County Medical Society recently elected officers to the two-year term which began January 1969.

The doctors elected: Peter Van B. Thorpe, MD, president; George Burgtorf, MD, vice-president; Art H. Panayis, MD, secretary; Theodore Shrop, MD, treasurer; and Thomas Herbert, MD, and Justinas Kudirka, MD, delegate and alternate to the Medical and Chirurgical Faculty of Maryland.

Kent County Medical Society

Jorge Oteiza, MD, was elected president of the Kent County Medical Society recently.

John S. Green, MD, was elected secretary-treasurer, and Harry Paul Ross, MD, was chosen as delegate to the Medical and Chirurgical Faculty of Maryland, with Oskar Gulbrandsen, MD, as alternate.

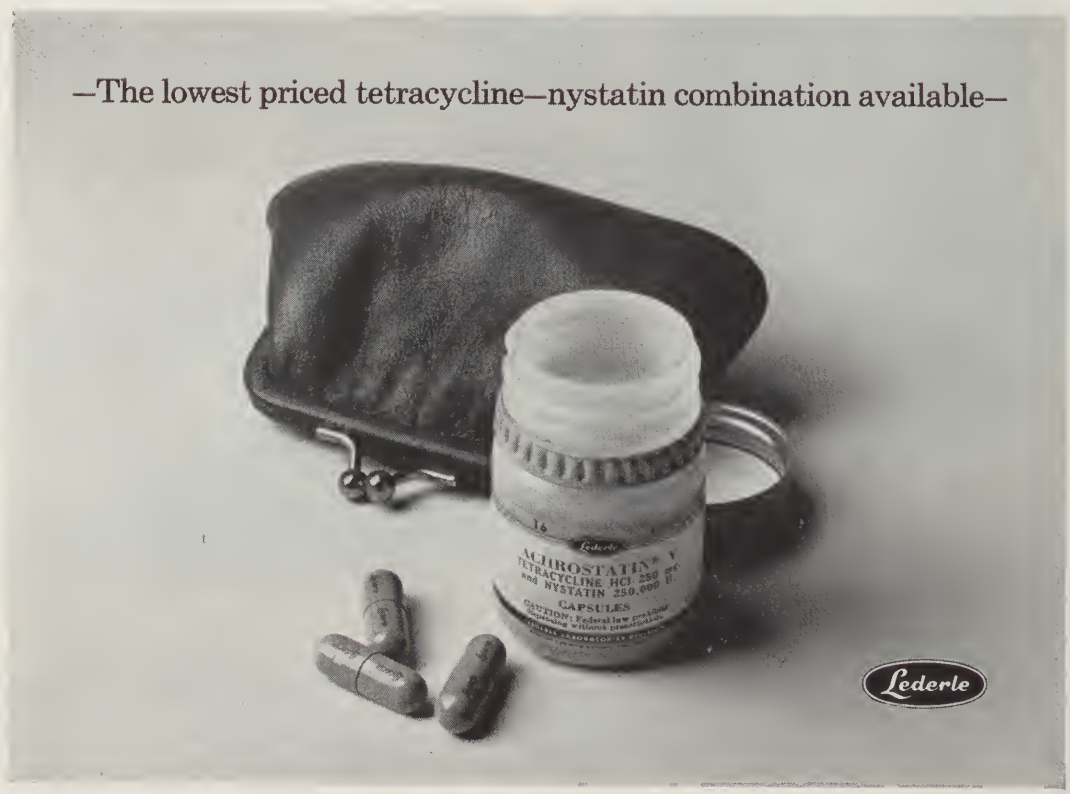
It was announced that Arthur F. Keefe, MD, has been appointed counselor to the Medical and Chirurgical Faculty of Maryland from the Eastern Shore area.

Prince Georges County Medical Society

William R. Greco, MD, of Riverdale, has been elected president of the Prince Georges County Medical Society for the calendar year 1969, succeeding Max M. Herzberg, MD, of Landover.

Other 1969 elected officials include John R. Buell, MD, of Laurel, who replaces Dr. Greco as vice president; S. Jack Sugar, MD, of Riverdale, who succeeds Dr. Buell as secretary; and Leon R. Levitsky, MD, of Mt. Rainier, who succeeds Dr. Sugar as treasurer.

Elected to serve two-year terms on the Society's Executive Board were John T. Lynn, MD, of Marlow Heights and A. Clark Holmes, MD, of Upper Marlboro.



Washington County Medical Society

At the annual meeting in November 1968, John H. Kehne, MD, turned the president's gavel over to Harold H. Gist, MD. Other elected officers are President-Elect E. W. Ditto, III, MD; Vice-President Sidney Novenstein, MD; Secretary R. H. Williams, MD; Treasurer E. B. Moody, MD; Delegates: Sidney Novenstein, MD, J. W. Banks, MD, and A. R. Cohen, MD.

In review, the year went like this. In January, Mr. Charles Greeb, Jr., president of First National Bank of Maryland, spoke of future projections for Washington County, indicating steady growth of the community—augmented somewhat by industrial expansions in adjacent Maryland counties and states.

In March, Dr. Fred Benjamin, chief physiologist with NASA, spoke on medical problems of manned space flight. John J. Dobbie, MD, "a dimunitive dynamo with a wry sense of humor and a great personality," was named Boss of the Year by Hager Chapter, National Secretaries Association at their Annual Executives night. His partner, James W. Banks, MD, was given a lifetime complimentary pass for his healing works

OF POSTGRADUATE PROGRAMS

presented through

Medical Education's Dedicated Instructional Channel

Supported in part by The Medical and Chirurgical Faculty and a grant from Merck, Sharp and Dohme.

Participating hospitals:

Anne Arundel General, Annapolis
Baltimore City, Baltimore
Baltimore County General, Randallstown
Bon Secours, Baltimore
Calvert County, Prince Frederick
Carroll County General, Westminster
Church Home, Baltimore
Cumberland Memorial, Cumberland
Easton Memorial, Easton
Eugene Leland Memorial, Riverdale
Franklin Square, Baltimore
Frederick Memorial, Frederick
Greater Baltimore Medical Center, Towson
Harford Memorial, Havre de Grace
The Johns Hopkins, Baltimore
Kent & Queen Anne's, Chestertown
Keswick, Baltimore
Lutheran, Baltimore
Maryland General, Baltimore
Mercy, Baltimore
Montgomery General, Olney
North Charles General, Baltimore
Peninsula General, Salisbury
Prince George's General, Cheverly
Provident, Baltimore
Rosewood State, Owings Mills
Sacred Heart, Cumberland
St. Agnes, Baltimore
St. Joseph, Baltimore
St. Mary's, Leonardtown
Sinai, Baltimore
South Baltimore General, Baltimore
Union Hospital of Cecil County, Elkton
Union Memorial, Baltimore
University of Maryland, Baltimore
Washington County, Hagerstown

Other Locations:

Medical and Chirurgical Faculty, Baltimore
State Office Building, Baltimore
Hospital Council of Maryland, Inc., Baltimore

MARCH 28, 1969—12:30 P.M.

CANCER OF THE BREAST

Edward F. Lewison, MD
Assistant Professor of Surgery
The Johns Hopkins University School of Medicine

A review of the historical and epidemiological aspects of breast cancer will be presented. Prompt detection and diagnosis will be discussed. Treatment will be considered from the standpoint of both the operable patient and the inoperable patient with advanced or metastatic disease.

Sponsor: Frederick Memorial Hospital

Replays: Monday, March 31, 1969 12:30 P.M.
Wednesday, April 2, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

APRIL 4, 1969—12:30 P.M.

URINARY TRACT INFECTION

John D. Young, MD
Professor of Urology
University of Maryland School of Medicine

There is increasing evidence that bacteria seldom invade the urinary tract without the help of some contributing factor such as injury to the urothelium or mechanical interference with urine flow. There is experimental evidence that "toxins" from E. coli have an inhibiting effect on ureteral peristalsis which might help perpetrate infection. The diagnosis and treatment of urinary tract infections is discussed with the above principles as a guide. Illustrative X-rays and diagrams will be shown.

Sponsor: Sacred Heart Hospital

Replays: Monday, April 7, 1969 12:30 P.M.
Wednesday, April 9, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

(Continued next page)

APRIL 18, 1969—12:30 P.M.
URINARY INCONTINENCE

Edward W. Campbell, MD
Assistant Professor of Urology
University of Maryland School of Medicine

Urinary incontinence will be considered as a symptom, representing a variety of clinical entities. While commonly a manifestation of local disease affecting the bladder and its supporting structures, incontinence may herald the onset of more distant and serious disease. Differential factors in the historical and physical manifestations of these various etiologic entities will be emphasized. Certain diagnostic procedures and treatment will be discussed.

Sponsor: Maryland General Hospital
Replays: Monday, April 21, 1969 12:30 P.M.
Wednesday, April 23, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

APRIL 25, 1969—12:30 P.M.
MALIGNANCIES OF THE CENTRAL NERVOUS SYSTEM

John A. Wagner, MD
Professor of Neuropathology
University of Maryland School of Medicine

The subject of intracranial tumor is reviewed with appropriate clinical-pathologic correlation. The salient features of the more important primary and secondary tumors is reviewed. Included also are notes on pathogenesis, relation to trauma and present status of research.

Sponsor: Frederick Memorial Hospital
Replays: Monday, April 28, 1969 12:30 P.M.
Wednesday, April 30, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

MAY 2, 1969—12:30 P.M.
CARCINOMA OF THE THYROID

Joseph B. Workman, MD
Associate Professor of Medicine
University of Maryland School of Medicine

Current knowledge concerning the causes, clinical classifications and methods of therapy in thyroid carcinoma will be discussed. Emphasis will be placed on the effect of age at onset, pathologic type, duration of disease and type of therapy upon eventual outcome.

Sponsor: Peninsula General Hospital
Replays: Monday, May 5, 1969 12:30 P.M.
Wednesday, May 7, 1969

Nose clear as a whistle

(THANKS TO DIMETAPP®)

Dimetapp Extentabs® does an outstanding job of helping to clear up the stuffiness, drip and congestion of colds and upper respiratory allergies and infections. Each Extentab keeps working up to 12 hours. And for most patients drowsiness or overstimulation is unlikely. Try Dimetapp. It clearly works.

FOR UPPER RESPIRATORY ALLERGIES AND INFECTIONS

Dimetapp Extentabs®

Dimetane® (brompheniramine maleate), 12 mg.; phenylephrine HCl, 15 mg.; phenylpropanolamine HCl, 15 mg.

UP TO 12 HOURS CLEAR BREATHING ON ONE TABLET

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripheral vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

A.H. ROBINS COMPANY
RICHMOND, VA. 23220

A·H·ROBINS

Owner Breaks Arm When Yacht Runs Aground

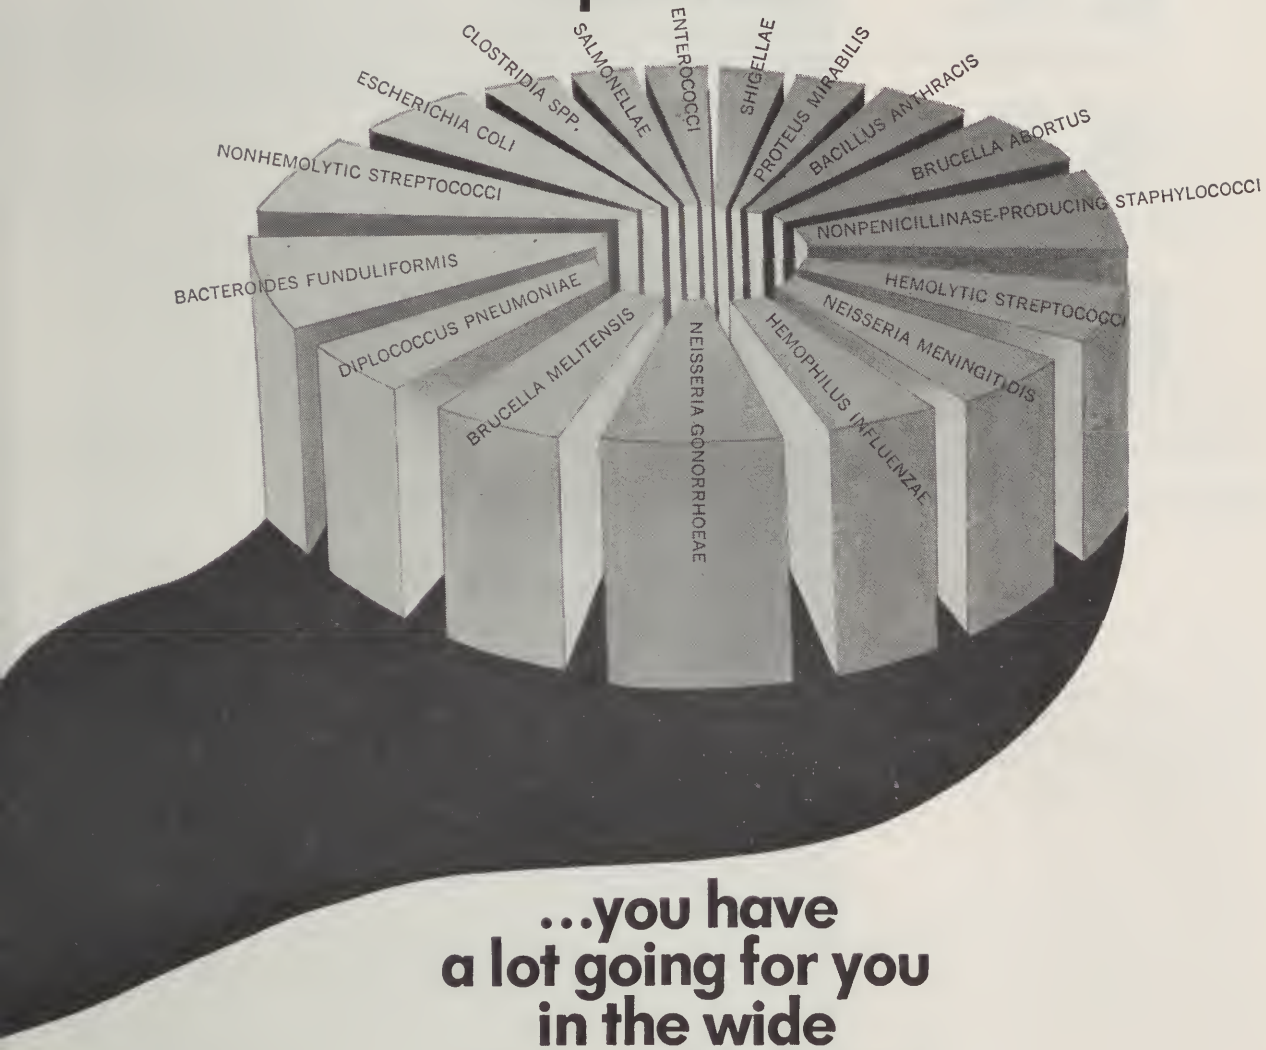
Schuyler, Oct. 31. Harry Waters of Covesville incurred a fractured arm ... tially capsized. The fire departm... had to rescue Waters by small ... Damage to the yacht is estimate...

Hasn't the skipper had enough excitement for one day?

For the patient who has been through an accident, the worry and anxiety following the mishap may actually heighten the perception of pain. This is why there's a classic ¼ grain *sedative* dose of phenobarbital in Phenaphen with Codeine—to take the nervous "edge" off, so the rest of the formula can control the pain more effectively.

A.H. Robins Company, Richmond, Va. 23220 A·H·ROBINS

Phenaphen® with Codeine



Phenaphen with Codeine Nos. 2, 3, or 4 contains: Phenobarbital (¼ gr.), 16.2 mg. (warning: may be habit forming); Aspirin (2½ gr.), 162.0 mg.; Phenacetin (3 gr.), 194.0 mg.; Hyoscyamine sulfate, 0.031 mg.; Codeine Phosphate, ¼ gr. (No. 2), ½ gr. (No. 3), or 1 gr. (No. 4) (warning: may be habit forming).

The compound analgesic that calms instead of caffeinates

Indications: Phenaphen with Codeine provides relief in severer grades of pain, on low codeine dosage, with minimal possibility of side effects. Its use frequently makes unnecessary the use of addicting narcotics. Contraindications: Hypersensitivity to any of the components. Precautions: As with all phenacetin-containing products excessive or prolonged use should be avoided. Side effects: Side effects are uncommon, although nausea, constipation and drowsiness may occur. Dosage: Phenaphen No. 2 and No. 3—1 or 2 capsules every 3 to 4 hours as needed; Phenaphen No. 4—1 capsule every 3 to 4 hours as needed. For further details see product literature.

With the broad Polycillin (ampicillin trihydrate) spectrum...

...you have a lot going for you in the wide range of bacterial infections.

PRESCRIBING INFORMATION. For complete information consult Official Package Circular. **Indications:** Infections due to susceptible strains of Gram-negative bacteria (including Shigellae, *S. typhosa* and other Salmonellae, *E. coli, H. influenzae, P. mirabilis, N. gonorrhoeae* and *N. meningitidis*) and Gram-positive bacteria (including streptococci, pneumococci and nonpenicillinase-producing staphylococci). **Contraindications:** A history of allergic reactions to penicillins or cephalosporins and infections due to penicillinase-producing organisms. **Precautions.** Typical penicillin-allergic reactions may occur, especially in hypersensitive patients. Mycotic or bacterial superinfections may occur. Experience in newborn and premature infants is limited and caution should be used in treatment, with frequent organ function evaluations. Safety for use in pregnancy is not established. In gonorrheal therapy, serologic tests for syphilis should be performed initially and monthly for 4 months. Assess renal, hepatic and hematopoietic function intermittently during long-term therapy. **Adverse Reactions:** Skin rash, pruritus, urticaria, nausea, vomiting, diarrhea and anaphylactic reactions. Mild transient elevations of SGOT or SGPT have been noted. Black tongue has been noted in some patients receiving the Chewable Tablets. **Usual Dosage:** Adults—250 or 500 mg. q. 6 h. (according to infection site and offending organisms). Children—50-100 mg./Kg./day in 3 to 4 divided doses (depending on infection site and offending organisms). Bacterial meningitis —150-200 mg./Kg./day in 6 to 8 divided doses. Children weighing more than 20 Kg. should be given an adult dose when prescribing orally. In parenteral administration, children weighing more than 40 Kg. should be given an adult dose. Beta-hemolytic streptococcal infections should be treated for at least 10 days. **Supplied:** Capsules—250 mg. in bottles of 24 and 100. 500 mg. in bottles of 16 and 100. For Oral Suspension—125 mg./5 ml. in 60, 80 and 150 ml. bottles. 250 mg./5 ml. in 80 and 150 ml. bottles. Chewable Tablets—125 mg. in bottles of 40. Injectable—for I.M./I.V. use—vials of 125 mg., 250 mg., 500 mg., and 1 Gm. Pediatric Drops—100 mg./ml. in 20 ml. bottles.

Rx

Valium® (diazepam) *t.i.d.* and *h.s.*

B.A. (*cum laude*)...V.P. (at thirty-two)...symbols that illuminate the quality of a life...the satisfactions of achievement, as well as its price...the pressures and stresses that can often create cardiac manifestations of psychic tension. For this kind of patient—with no demonstrable pathology—consider the singular benefits of Valium (diazepam).

With its pronounced calming action, Valium can relieve psychic tension promptly, attenuating its somatic signs and symptoms. Further, Valium is distinctly useful when somatic and depressive symptomatology (secondary to psychic tension) coexist. And Valium is generally well tolerated; in proper maintenance dosage, it seldom dulls the senses or interferes with functioning.

When psychic tension-related insomnia appears, an *h.s.* dose added to the *t.i.d.* schedule helps promote sleep.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

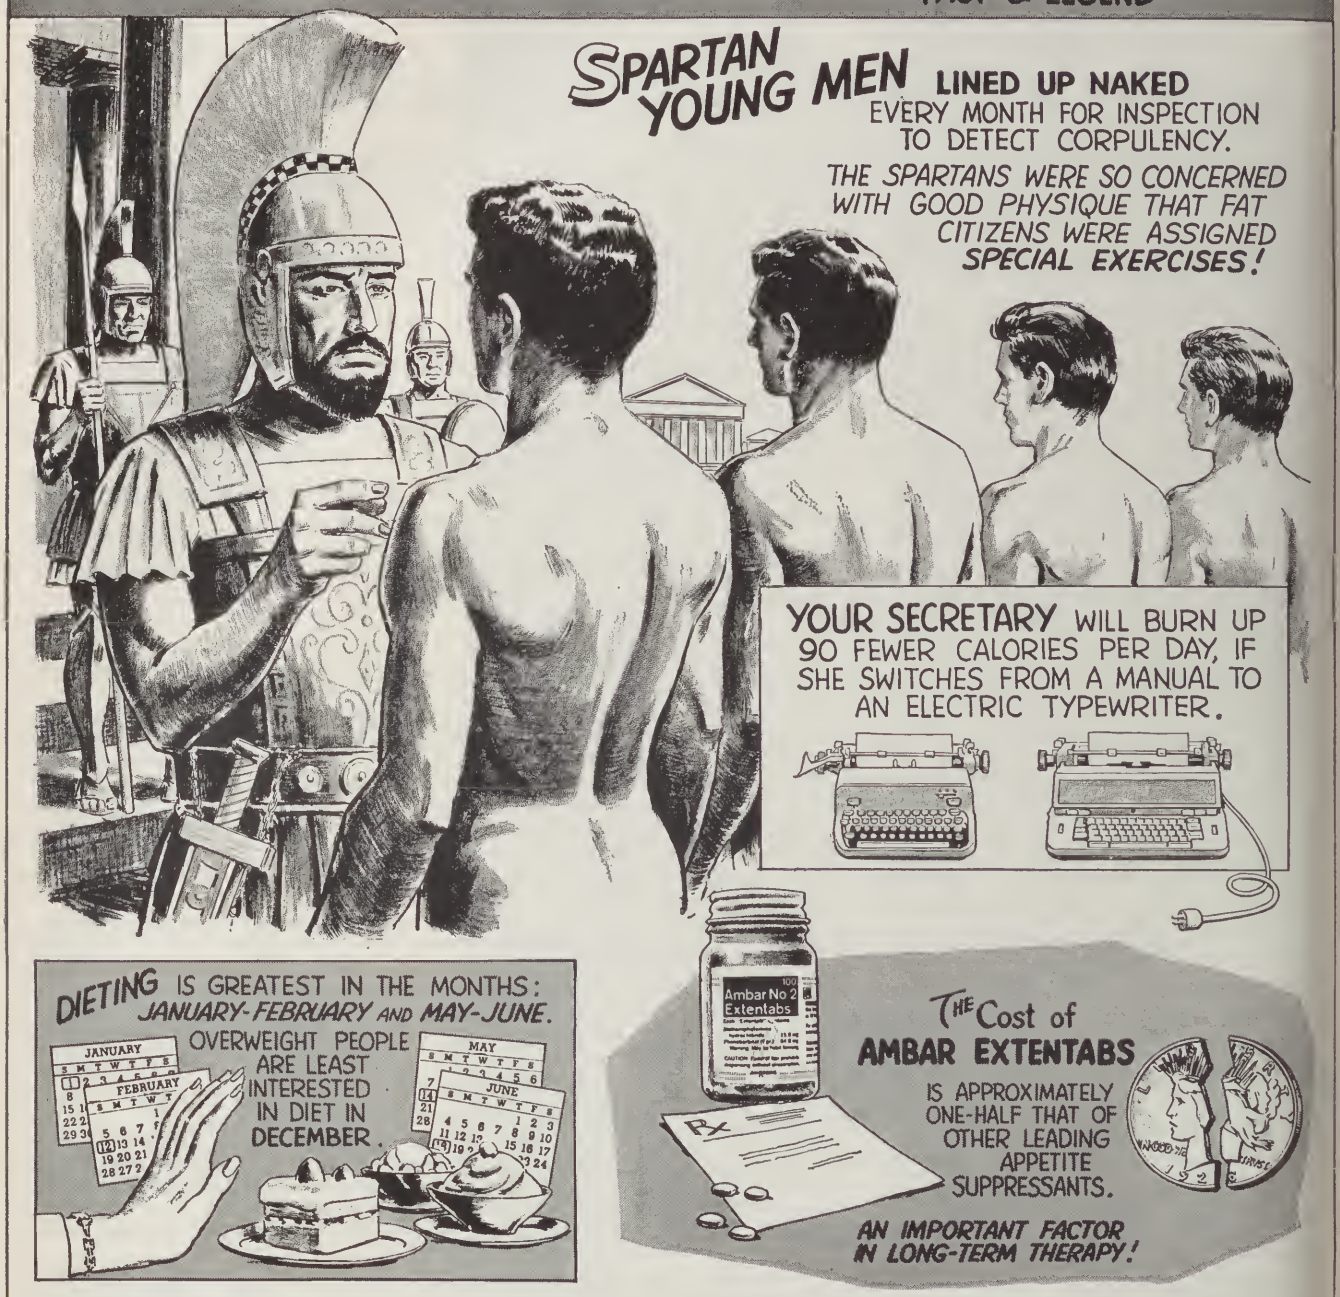
Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms have occurred following abrupt discontinuance. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation, have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Valium® (diazepam)



2-mg, 5-mg, 10-mg tablets *t.i.d.* or *q.i.d.*

to help relieve psychic tension
and its somatic symptoms

The AMBAR SCRAPBOOK of

Obesity Oddities

FACT & LEGEND

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg.,
phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety...helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

A. H. ROBINS COMPANY,
RICHMOND, VA. 23220

A·H·ROBINS

Let's be specific about Campbell's Soups... and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

No two women are quite alike...

and no other oral contraceptive is quite like Ovulen-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

The progestin is distinctive, and for some women this may mean a different clinical response. The Compack® tablet dispenser is distinctive; its functional simplicity makes it virtually patient-proof. The acceptance of Ovulen-21 is distinctive... together with Ovulen®, it is more often prescribed than any other individual contraceptive product currently available.

Indication—Oral contraception.

Contraindications—Thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia, undiagnosed abnormal genital bleeding.

Warnings—Watch for the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism, retinal thrombosis); if present or suspected discontinue the drug immediately.

British studies reported in April 1968[1,2] estimate there is a seven- to tenfold increase in mortality and morbidity due to thromboembolic diseases in women taking oral contraceptives. In these controlled retrospective studies, involving 36 reported deaths and 58 hospitalizations due to "idiopathic" thromboembolism, statistical evaluation indicated that the differences observed between users and non-users were highly significant. The conclusions reached in the studies are summarized in the table below:

Comparison of Mortality and Hospitalization Rates Due to Thromboembolic Disease in Users and Non-Users of Oral Contraceptives in Britain.

Category	Mortality Rates		Hospitalization Rates (Morbidity)
	Age 20-34	Age 35-44	Age 20-44
Users of Oral Contraceptives	1.5/100,000	3.9/100,000	47/100,000
Non-Users	0.2/100,000	0.5/100,000	5/100,000

No comparable studies are yet available in the United States. The British data, especially as they indicate the magnitude of the increased risk to the individual patient, cannot be applied directly to women in other countries in which the incidences of spontaneously occurring thromboembolic disease may differ.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or sudden onset of proptosis, diplopia or migraine. Withdraw medication if papilledema or retinal vascular lesions are found.

Since the safety of Ovulen in pregnancy has not been demonstrated, it is recommended that pregnancy be ruled out for any patient who has missed two consecutive periods before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the first missed period.

A small fraction of the hormone agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—Pretreatment physical examination should include special reference to the breasts and pelvic organs, and a Papanicolaou smear.

Endocrine and possibly liver function tests may be affected by Ovulen. Therefore, it is recommended that such tests if abnormal be repeated after the drug has been withdrawn for two months.

Pre-existing uterine fibromyomas may increase in size under the influence of progestogen-estrogen preparations.

Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation.

In breakthrough bleeding, and all irregular vaginal bleeding, consider nonfunctional causes. Adequate diagnostic measures are indicated in undiagnosed vaginal bleeding.

Carefully observe patients with a history of psychic depression and discontinue the drug if severe depression recurs.

Any possible influence of prolonged Ovulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study.

A decrease in glucose tolerance has occurred in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be observed carefully while receiving Ovulen.

Because of the effects of estrogens on epiphyseal closure Ovulen should be used judiciously in young patients in whom bone growth is not complete.

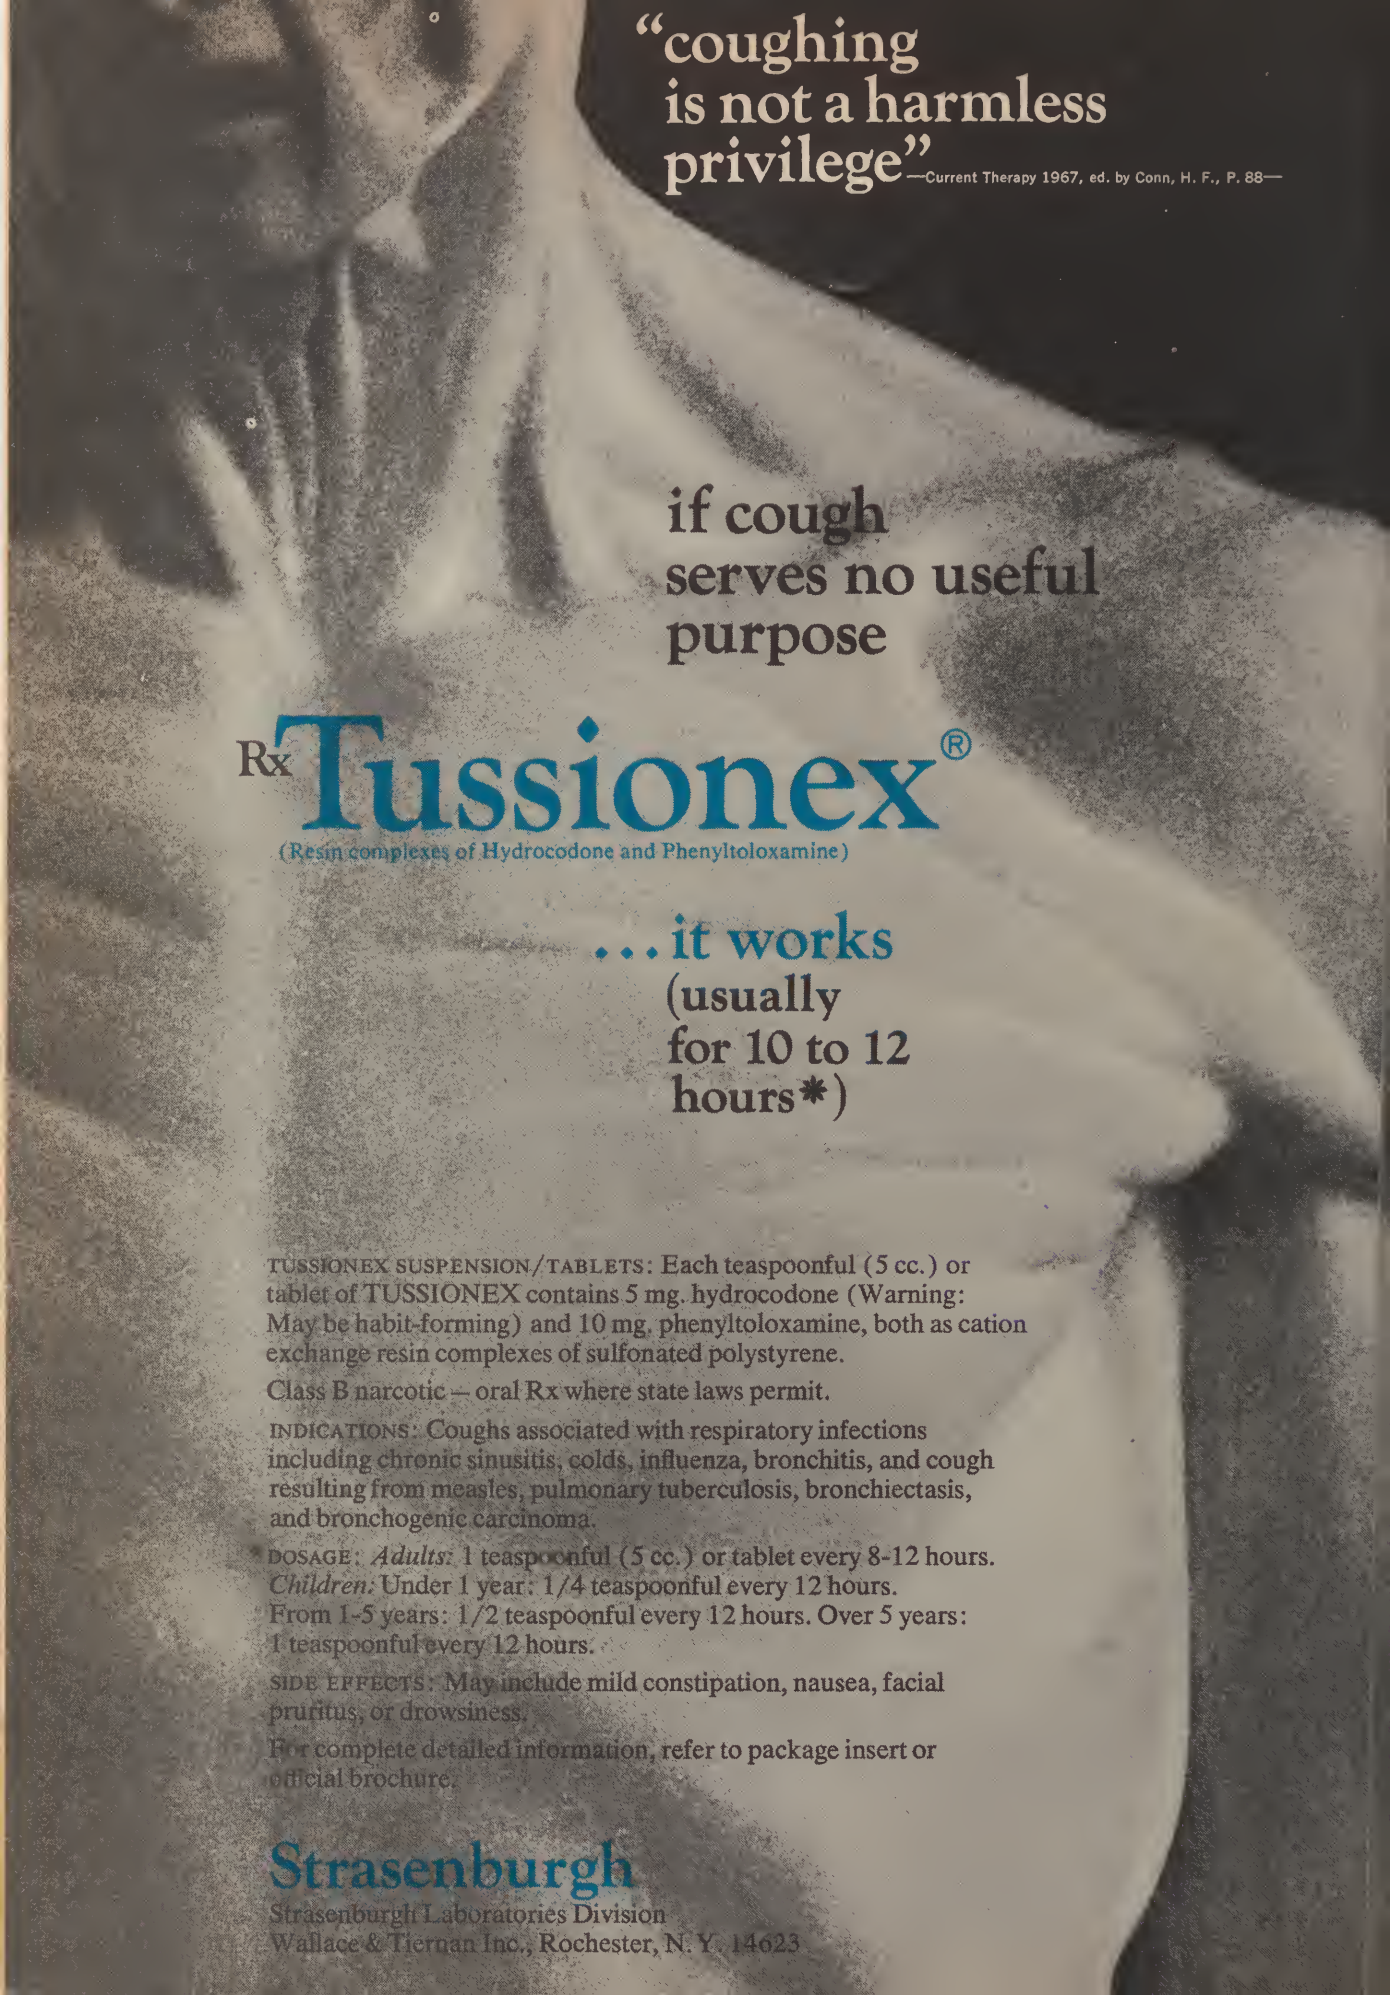
The age of the patient constitutes no absolute limiting factor, although Ovulen therapy may mask the onset of the climacteric.

The pathologist should be informed of Ovulen therapy when relevant specimens are submitted.

Adverse Reactions—A statistically significant association has been shown between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: cerebrovascular accidents, neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement, secretion), change in weight, changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, allergic rash, rise in blood pressure in susceptible individuals, mental depression.



Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme and nodosum, hemorrhagic eruption, itching.

The following laboratory results may be altered by oral contraceptives: hepatic function: increased sulfobromophthalein and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T^3 uptake values; metyrapone test; pregnanediol determination.

SEARLE Where "The Pill" Began
G. D. SEARLE & CO., P. O. Box 5110, Chicago, Illinois 60680

TUSSIONEX SUSPENSION/TABLETS: Each teaspoonful (5 cc.) or tablet of TUSSIONEX contains 5 mg. hydrocodone (Warning: May be habit-forming) and 10 mg. phenyltoloxamine, both as cation exchange resin complexes of sulfonated polystyrene.

Class B narcotic — oral Rx where state laws permit.

INDICATIONS: Coughs associated with respiratory infections including chronic sinusitis, colds, influenza, bronchitis, and cough resulting from measles, pulmonary tuberculosis, bronchiectasis, and bronchogenic carcinoma.

DOSAGE: *Adults:* 1 teaspoonful (5 cc.) or tablet every 8-12 hours. *Children:* Under 1 year: 1/4 teaspoonful every 12 hours. From 1-5 years: 1/2 teaspoonful every 12 hours. Over 5 years: 1 teaspoonful every 12 hours.

SIDE EFFECTS: May include mild constipation, nausea, facial pruritus, or drowsiness.

For complete detailed information, refer to package insert or official brochure.

Strasenburgh Laboratories Division
Wallace & Tiernan Inc., Rochester, N. Y. 14623

For the "Cheater Eater"

Formulas: Each 'Dexamyl' *Spansule* capsule No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid (Warning, may be habit forming). Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital (Warning, may be habit forming).
Before prescribing, see complete prescribing information in SK&F literature or *PDR*.
Contraindications: Hyperexcitability, undue restlessness, hyperthyroidism, porphyria; in patients on MAO inhibitors.
Precautions: Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Excessive use of the amphetamines by unstable individuals may result in a psychological dependence. Rarely, symptoms of toxic psychosis (hallucinations, confusion, panic states, etc.) may occur with amphetamines, usually after prolonged high dosage. In these instances, withdraw the medication. Use cautiously in pregnant patients, especially in the first trimester.
Adverse Reactions: Overstimulation, restlessness, insomnia, g.i. disturbances, diarrhea, palpitation, tachycardia, elevated blood pressure, tremor, sweating, impotence and headache.
Supplied: In bottles of 50.

DIA-QUEL actually tastes good

DIA-quel contains the only therapeutically active ingredient of paregoric—tincture of opium. This has been combined with homatropine methylbromide and pectin to make a sensible antidiarrheal formula.

By leaving out paregoric's outdated preservative—bitter-tasting camphor—we've produced an antidiarrheal that is good-tasting, as well as effective and prompt-acting in acute, nonspecific diarrheas and their accompanying "cramps." It is DIA-quel, a clear, red liquid with a pleasant cherry flavor.

Each teaspoonful (5 ml.) of DIA-quel Liquid contains:
Tincture of Opium... 0.03 ml.—Equivalent to 0.75 ml. of paregoric.
(Warning: May be habit forming)
To reduce hypermotility and frequency.
Homatropine Methylbromide... 0.15 mg.
A safe dose for mild spasmolysis to curb cramping and griping.
Pectin... 24. mg.
Demulcent, adsorbent. Helps form stools.
Alcohol 10% by volume.

In case you're curious, back in the 1700's paregoric was being used for diarrhea, but since the state of the pharmaceutical art was extremely primitive, fungus growth in the medication was a problem. Bitter-tasting camphor was added to prevent such growth and anise oil was added in an attempt to cover up the camphor taste. DIA-quel Liquid is a modern formulation that does not contain either of these outdated ingredients.

Caution: With use of DIA-quel Liquid observe the usual precautions associated with opium derivatives and anticholinergics.

Dosage: Usual adult dosage: 1 or 2 tablespoonfuls (15 or 30 ml.) t.i.d. or q.i.d. Usual children's dosage (Clark's rule): ½ to 2 teaspoonfuls (2.5 to 10 ml.) t.i.d. or q.i.d.

How Supplied: In 4 fl. oz. (118 ml.) band-sealed bottles.

DIA-quel is a Federally exempt narcotic (Class X) preparation. Where state law permits, no prescription is necessary.

For a complimentary sample of DIA-quel, simply mail your request to us on a signed prescription blank.

MEDICAL NEWS

Abraham M. Lilienfeld, MD, Chairman of the Department of Chronic Diseases at The Johns Hopkins School of Hygiene and Public Health, was recently awarded the 1968 Bronfman Prize of $5,000, an engraved scroll, and a crystal cube from the American Public Health Association for his generosity "in sharing ideas and . . . giving counsel . . . valuable assistance to students, investigators, and agencies concerned with the investigation and control of chronic diseases."

Dr. Lilienfeld was also cited as being "distinguished by a singular lack of self-interest, a great willingness to help others, and a tireless devotion to the advancement of epidemiology."

The award was instituted in 1961 as a result of a grant from the Samuel Bronfman Foundation. It is international in scope and was designed to encourage creative, pioneering work in the field of public health.

Dr. Lilienfeld's department of chronic diseases develops studies in genetics, biological aspects of chronic diseases, epidemiological, clinical, and public health aspects. The department trains graduate students in research methodology.

Other recipients of the 1968 award are **James L. Goddard,** former Commissioner of the Food and Drug Administration, and **Moises Behar,** Director of the Institute of Nutrition of Central America and Panama.

* * *

Two Maryland physicians were among the 119 radiologists who became fellows of the American College of Radiology at its annual meeting in Chicago in the latter part of February.

William S. Cole, MD, Rockville, and **Carl W. Boyer, Jr., MD,** Adelphi, received the degree of fellow for their distinguished service to their specialty. Of the 7,000 members of the college, fewer than 1,200 have been awarded the degree.

* * *

Archie B. Hooton, MD, has joined the medical staff at Taylor Manor Hospital in Ellicott City as a fulltime psychiatrist. Dr. Hooton received his MD degree from the University of Geneva, Switzerland. He has served on the staffs of St. Agnes Hospital, Spring Grove State Hospital, and Seton Institute.

* * *

During the AMA meeting in Miami last December, **Samuel Livingston, MD,** displayed his award-winning exhibit on epilepsy.

The exhibit describes the recent diagnostic and therapeutic advances which have been made in the field of epilepsy.

Dr. Livingston is Director and Physician-in-Charge of The Johns Hopkins Epilepsy Clinic.

* * *

Carolyn S. Pincock, MD, was installed as Second Vice-President of the American Medical Women's Association during the Inaugural Banquet in Boston, Massachusetts, at the Statler Hilton Hotel. Dr. Pincock was the President of Branch No. 1, Washington, D.C. for 1948-49. In June 1968, she was a Councilor at the Medical Women's International Association XI Congress in Vienna, Austria.

* * *

Michael R. Dobridge, MD, Silver Spring, has been named to the Board of the State Department of Social Services. He will complete the term of Mrs. Charles D. Harris which will terminate May 31, 1971.

* * *

Julius R. Krevans, MD, Professor of Medicine at The Johns Hopkins University School of Medicine and Physician-in-Chief at Baltimore City Hospitals, will become Dean for Academic Affairs at the school of medicine on July 1, 1969.

As a key member of the administrative staff, Dr. Krevans will assume broad responsibility for the development of educational policies, including post-doctoral education and curriculum development.

Dr. Krevans joined the Hopkins staff in 1950 as a fellow in hematology. From 1951 to 1953, he served his residency in medicine at The Johns Hopkins Hospital, and was appointed director of the hospital's blood bank and an instructor in medicine in the university in 1953. He was promoted to assistant professor in 1955, associate professor in 1960,

and professor in 1968. From 1962 to 1963, he served as assistant dean for student affairs at the school of medicine.

In 1963, he was appointed Physician-in-chief of the Baltimore City Hospitals.

Dr. Krevans was appointed a member of the Planning Council for the State of Maryland Board of Health and Mental Hygiene in 1964, and since 1965 he has been a member of the medical advisory committee to the national board of trustees of the Leukemia Society, Inc.

* * *

On Tuesday, February 18, **Fred N. Cole, Jr., MD,** addressed The Professional Forum at its monthly dinner meeting at the Baltimore Country Club.

Dr. Cole's address, *The Professional Man—A Conservative in a Liberal World,* touched upon various aspects of the Medicare and Medicaid Programs; and was followed by a round-table discussion.

Established in 1965, The Professional Forum is an interdisciplinary group drawn from all of the professions. Chairman of the committee on medicine is William E. Gilmore, MD. The program was arranged by J. E. Rytten, president.

* * *

Jacob H. Conn, MD, Assistant Professor of Psychiatry at The Johns Hopkins University School of Medicine, has received the Award for the best paper on clinical hypnosis presented in 1968. The Award and Certificate of Merit was presented for his paper on *Hypnosynthesis,* by the Society for Clinical and Experimental Hypnosis at the 20th Scientific Annual Meeting at the University of Chicago in November.

Dr. Conn is a past president of the American Board of Medical Hypnosis and of the National Society for Clinical and Experimental Hypnosis. He has been Acting Chief Medical Officer of the Supreme Bench of Baltimore, past president of the Maryland Association of Private Practicing Psychiatrists, and Consultant to the U.S. District Court, Public Health Service and the Veterans Administration.

In 1960 he was the recipient of the Award for the Best Clinical Contribution to Scientific Hypnosis. In 1961, he received the Raginsky Bronze Plaque for Leadership and Achievement as a "distinguished psychiatrist, teacher, scientist and pioneer in the field of hypnotherapy." Other awards include the Schneck Award for his "Significant Contributions to the Development of Medical Hypnosis," and the SCEH Presidential Award for his "outstanding work in the field of hypnosis over a period of 25 years."

* * *

George C. Alderman, MD, Dudley C. Babb, MD, and **Samuel M. M. Lumpkin, MD,** have announced their new office address. Their practice of otolarygology will be conducted in the Charles Fountain Professional Building, 6301 North Charles St., Baltimore.

* * *

New diplomates of the American Board of Anesthesiology include **OK Hyung Kang, MD,** Silver Spring; **Sheppard Kaplow, MD, Thomas C. McAslan, MD,** and **Eugene J. Pantuck, MD,** Baltimore; **Sandor Paskin, MD,** Rockville, and **McKim Williams, MD,** Bethesda.

* * *

Andrew J. Brennan, MD, has announced the opening of his new office at Georgetown Doctors Park, 5415 West Cedar Lane, Bethesda.

Dr. Brennan is engaged in the practice of internal medicine and allergy.

* * *

As of June 1, 1969, the new professor and chairman of the Department of Public Health Administration of The Johns Hopkins University School of Hygiene and Public Health will be **Arthur Bushel, DDS, MPH.**

Dr. Bushel will succeed **Dean John C. Hume** who will continue to hold a teaching position in the department in addition to his responsibilities as Dean.

A dentist with extensive experience in public health administration, teaching and consultative work, Dr. Bushel received his graduate degrees from Columbia University. After completing his public health training, he became Assistant Director of the New York State Department of Health's Bureau of Dentistry; Director of Dentistry for the New York City Department of Health; Special Assistant Commissioner and Director of Dentistry and Assistant Commissioner for Professional Staff Services (New York City). He has been First Deputy Commissioner since 1966, and was Acting Commissioner of Health from January to May, 1966.

A new National Cancer Institute-Veterans Administration Medical Oncology Service has been established at the Washington, D.C. Veterans Administration Hospital. The service will function both as a part of the medicine branch of the National Cancer Institute, National Institutes of Health, and the Washington, D.C. Veterans Administration Hospital Medical Services.

Oleg S. Selawry, MD, former chief of chemotherapy at St. Jude's Children's Research Hospital, Memphis, Tennessee, will head the new service.

The service will plan and conduct clinical trials with new and established anti-cancer drugs and investigate the activity of new agents. It will also evaluate the possible role of the body's defense mechanisms in influencing the survival time and response to treatment of patients with lung cancer. In addition, Dr. Selawry and his associates will join investigators from other units of the National Cancer Institute's Clinical Trials Area in a study of cell kinetics in patients with solid tumors.

A 30-bed facility at the VA Hospital will be devoted to the cancer chemotherapy studies. At the present time, the unit has two senior investigators, a junior physician and a VA staff physician, in addition to Dr. Selawry.

The Leukemia Society of America has presented new guidelines for the administration of its Patient-Aid Program.

The Leukemia Society is a national voluntary health agency with chapters in over 60 cities. It is prepared to offer leukemia patients in need of assistance four basic types of aid:

- drugs used in the care, treatment, and control of leukemia
- laboratory fees
- transfusing of blood, including processing, typing and cross-matching
- transportation

Additional information about the Leukemia Society of America Patient-Aid Program may be obtained by writing or telephoning the society's local chapter offices or the national office at 211 East 43rd St., New York, N.Y. 10017.

* * *

C. Rollins Hanlon, MD, Professor of Surgery and Chairman of the Department of Surgery at St. Louis University School of Medicine, St. Louis, Missouri, has been named Director-Elect of the American College of Surgeons.

Dr. Hanlon will assume the directorship of the college soon after the close of the 1969 Clinical Congress in October.

A graduate of Loyola College, Baltimore, Dr. Hanlon received his MD degree from The Johns Hopkins University School of Medicine in 1938. He interned in surgery at The Johns Hopkins Hospital and served as the W. S. Halsted Fellow in Surgery. He was instructor and resident in surgery and later became associate professor of surgery before assuming his present position at St. Louis University and surgeon-in-chief of the St. Louis University Hospitals.

* * *

The Johns Hopkins Medical Institutions have announced the appointment of **Torrey C. Brown, MD,** as head of the development of the Hopkins' out-of-hospital health care programs in East Baltimore.

Dr. Brown, an Assistant Professor of Medicine at the school of medicine and a physician on the hospital staff, will be an Associate Director of the Office of Health Care Programs, which was formed in December by actions of the university and hospital boards of trustees.

Initially, Dr. Brown's efforts will be in planning a comprehensive health care system for the community combining the services of local physicians, other hospitals, the City Health Department, the Model Cities Agency, and other existing agencies.

MED-CHI ANNUAL MEETING

APRIL 9, 10, 11

For information on the happenings,

see pages 25, 27 and 29.

The Preceptorship Program of the

One of the principal projects of the Maryland Academy of General Practice this past summer was the initiation of a preceptorship program. The Academy provided a stipend for the students interested in having this experience.

Although the MAGP's main medical interest lies in the area of family practice, preceptorship programs are not solely a function of the family physician. The purpose of this article is to allow both the student and the preceptor to describe this new experience and to encourage other medical groups to become involved in similar programs.

Mr. John Wilson, one of the students, is completing his medical school training at the University of Maryland. Regardless of the direction of his medical future, the time spent last summer in the preceptorship program will certainly broaden his medical horizons.

J. Patrick Jarboe, MD, from Great Mills in St. Mary's County, was one of Mr. Wilson's

What's in a

For the Physician

J. PATRICK JARBOE, MD
Great Mills, Maryland

Due to several circumstances last spring, I was given the unexpected opportunity to have a preceptee audit my practice. I found I had much ambivalence concerning this possibility. Being a solo family physician in a rural area is a lonesome business and the thought of professional companionship for a month was enticing. But would the quality of care in my practice bear scrutiny? Would some brash young man from the ivory tower make my life miserable for a month by pointing out my inadequacies or acting supercilious? (You see, I'm young enough to remember the attitudes of some of my classmates in medical school.)

However, my curiosity won out, and the month of July brought to my office and home a truly delightful young man. My three children adopted him as a member of the family. My patients accepted him as my colleague. No one objected to his presence.

For my part, I began to see my patients in a different light, as they must appear to this young man. I began to more objectively consider my therapy for their various ills. My temporary colleague and I discussed the merits of various treatment plans, and I believe we both learned as a result.

The main reason for the good outcome of this project was that the young man whom I met was a fine human being. He was intelligent, friendly, and altogether fair in his approach. I only hope he benefited from the experience as much as I did.

Maryland Academy of General Practice

four preceptors. Dr. Jarboe has a very active practice, one of the most demanding in the county. He is also very active in civic affairs and has made substantial contributions to the development of St. Mary's County.

Qualifications such as these are important in the selection of preceptors. It is precisely this experience at the interfaces of professional, social and civic responsibilities that formal medical school training is unable to provide. The opportunity for the student-doctor to see how the family physician fits into and contributes to his community is a prime objective of the academy's preceptorship program.

LEON W. BERUBE, MD, PRESIDENT
Maryland Academy of General Practice

Preceptorship?

For the Student

JOHN WILSON
Student, University of Maryland
School of Medicine

The drive down to Southern Maryland July 1 was hot, but fast. Just two hours from Baltimore, my first experience in the private practice of medicine awaited. About ten minutes after meeting my general practice preceptor, he was called next door to see a neighbor who had an acute myocardial infarction. By the time an ambulance had left for the hospital, I felt as though my adventure in medicine had begun.

My interest in general practice is long standing, and like most students who have a special field of interest, I was very anxious to find out what that specialty was like in everyday, actual practice. SAMA has had a six-week preceptorship program available for years through the Sears-Roebuck Medical Foundation. Originally I had applied for that and was accepted; however, there isn't a Sears-Roebuck medical center in the State of Maryland, and for personal reasons I wanted to stay here. Having declined the SAMA offer, I heard about the Maryland Academy of General Practice preceptorship program of similar design. The academy's program is eight-weeks long; usually four weeks with two different general practitioners selected from areas in which the student would like to live, or to which he would like to commute. Since I wanted to see what rural family practice was like, I decided to accept an assignment in Southern Maryland for a month. My second month was to be spent in Hagerstown with four different GP's, a week's time with each. Dr. James Jarboe, the preceptor with

whom I spent July, is a young man, a University of Maryland graduate, and I feel, an excellent clinician. Both he and his wife and three children made my stay in St. Mary's County very pleasant and educational. Although we all profited from the month, undoubtedly I owe the greater debt, for the amount of material I learned at this stage of my career will be invaluable, no matter what future I might have.

The everyday practice of family medicine would amaze most medical students. One of the first patients I saw was an old farmer who hadn't been to a physician for 20 years. He had severe, far advanced rheumatoid arthritis involving most of his joints, and yet, his only complaint was that he couldn't get along as well as he used to driving his tractor. In the hospital, one of the first patients was a ninety-four-year-old Negro lady who had diabetes, several paralyzed limbs, and gangrene of the toes and foot on one side. She had been scheduled for surgery several times, but cancelled because of acute bouts of pneumonia. She was finally done under local infiltration anesthesia and did well. However, she died two days later, rather suddenly. Later that night while we were in the Emergency Room, a middle-aged woman came in and handed Dr. Jarboe a placenta in a paper towel. Early the next morning before breakfast, we got a call from the hospital about one of our OB patients who was about to deliver. When we arrived there I began to scrub for the delivery. Just as the girl started to crown, Dr. Jarboe was called for a cardiac arrest on the patient he admitted the first day of July. I was left holding the baby and bag literally, but fortunately everything went according to nature. Later that morning office hours, as always, brought interesting patients. Perhaps one quarter to one third of the patients a GP sees have dermatological lesions. I saw patients with classical lesions of erythema multiforme, erythema nodosum, lichen planus, and even a case of sarcoidosis, first discovered because of cutaneous manifestations. Many cases of atopic, seborrheic, and contact dermatitis appeared daily. For the first time in my medical career, diagnosing and treating these conditions became a lot of fun. Ear, nose, and throat exams and disorders are also quite important in general practice. A large number of people come to a doctor because of ENT allergic manifestations. Problems of management of an allergic patient there can be very difficult because of financial and logistic considerations. I soon learned that management of every patient is not always one-two-three, as stated in the text books and often heard at medical centers. It is important to be able to quote the theoretically correct therapy for a certain condition, but at times deliverance or implementation of that choice is literally impossible.

I frequently saw patients with the common diseases and complaints that are prevalent in most communities in the United States: diabetes, cardiovascular disease, especially hypertension, chronic obstructive pulmonary disease, menopausal symptoms, osteoarthritis, headaches, URI's, and of course, cancer of all types. The list of conditions could go on ad infinitum because in the course of a month, one sees well over a thousand patients and just about every category of disease. Some of the patients had rarer conditions and usually classic forms of their illness. A young housewife had had mild prodromata and subsequently developed characteristic pleurodynia. A fifty-year-old man had a text book case of rheumatic heart disease with mitral stenosis. After some relatively minor stress his disease again began to decompensate and develop into pulmonary edema. This time he was convinced he should have surgical correction.

Perhaps I should mention that none of the GP's with whom I lived did any but the most minor surgery, mainly lacerations and mole removal type of procedures. However, on one occasion we were greeted with a comical situation calling for a sure knife. One of Dr. Jarboe's patients, an old friendly man with Parkinsonism, appeared on the back porch of our office building with his penis caught in his pants zipper. After working to free it for about two hours, he finally thought it time to call for help, but said he didn't know whether to see a doctor or a blacksmith. We had to do a partial circumcision in the office to relieve his embarrassment.

At the end of the month, my wife and I spent a well-deserved weekend together. Unfortunately she couldn't accompany me the entire time, but we were able to see each other about every other weekend.

Hagerstown has a population of about 40,000 with another 40 to 50,000 in surrounding com-

munities. The four general practitioners with whom I worked were in an association of sorts, which allowed each of them to have at least every other weekend off and three out of four Thursday afternoons off. All had separate offices and slightly different types of practices.

My first night's sleep in Hagerstown was interrupted at 3 AM by a hospital call for a delivery. My preceptor and I raced across town in his TR-4 with the convertible top down. By the time I got there I was wide awake and ready to catch the baby. Office hours the next day seemed long, but not as long as the next day after we again had been called the second consecutive night for a delivery which turned into a Caesarean section.

Many of the patients in Hagerstown had conditions similar to those I've already mentioned. However, a few stand out as different and unusual for many reasons. I made a house call on a middle-aged man with a familial type of progressive muscular dystrophy. The disease was present in typical form and had manifested itself in his family, in his brother and uncle, and could be traced to progenitors in Germany. In his case, as in others of a chronic and progressive nature, one looks for practical things which can help the patient withstand the emotional and physical devastation associated with their process. The value of a personal physician's concern and consolation to a patient of this sort was again reinforced in my mind.

Two of the other physicians with whom I lived were County Medical Examiners for Washington County. On one occasion we got a call from the State Police about an old man who had been found dead in bed. When we got there we could smell the decomposing body as soon as we got out of the car. He had been dead for about three days and had lain in a hot room. There must have been a hundred thousand flies in the dilapidated old room, and the smell was truly unbelievable. Later that day the odor which had permeated my clothes was still noticeable. After showering and changing clothes, I could feel clean enough to again enter the world of the living.

I'll mention a few other things which most students don't see in school, and yet will be important in private practice. Cases of chickenpox, rubella, and roseola are commonly seen, and yet I had never seen a case of rubeola, or seven-day measles until this summer when fairly characteristic disease was present in two siblings who hadn't been vaccinated.

Counseling in general, and marriage counseling in particular, becomes a difficult therapeutic challenge to the family practitioner whom I feel is in a unique position to help. Frequently, one hears the story of the young couple who "had to get married", and now he's being unfaithful and she's frigid. Another extremely common problem is the alcoholic father or mother or both who have an asthmatic child. Occasionally the undiagnosed, previously unseen, schizophrenic will walk into the office and describe delusions and hallucinations. More and more frequently these days, teen-agers are being seen in the office and emergency room because of drug or glue abuse or both.

The things I saw this summer in the individual patient were made all the more interesting because of being able to see the family interactions in relation to the disease. Anyone in any type of private practice will have to treat the family as well as the patient.

I could write much more about medical aspects of my summer preceptorship, and I could write even more about economic and practical considerations in establishing a private practice, but I'll let the reader discover those things for himself. My highest recommendations to the Maryland Academy of General Practice and its summer program.

———O———

Alcoholism – Obesity "Sans" Teeth?

Both the alcoholic and the obese patient have much in common in their behavior, *ie*, particularly the route of input. Both behaviors—eating and drinking—are not detrimental per se, but with an increase in frequency there is also a decrease and exclusion of other alternative, more adaptive behaviors. Because over-eating or over-drinking is essentially a sociological phenomenon, where some evidence would point to the dependency also being an expression of cognitive style, social therapy would seem appropriate. The alcoholic is a person within a social system who has a limited number of ways to behave within that system. By placing him in a social system such as Alcoholics Anonymous or group therapy, new behaviors or behavioral modifications may occur and thus open up new, more adaptive alternative ways of behaving within the social system. However, the social system, to be therapeutic, must also be open so that when each alcoholic patient hits a stumbling block and regresses to prior alcoholic behaviors, the therapeutic system (be it Alcoholics Anonymous, group therapy, family therapy, or even individual therapy) must be able to allow for this episode and utilize it for further work. The treatment of the alcoholic, as with the obese, is not merely a medical or a social problem but is both, and both systems should be complementary to each other rather than being competitive or mutually exclusive.

MERRILL I. BERMAN, MD
Assistant Chief, Psychiatry Service
Public Health Service Hospital
San Francisco

The similarities between polydipsia (alcoholism) and polyphagia (obesity) have been noted for some time, and these behavioral similarities were brought out during group therapy sessions with obese patients in an anti-obesity clinic.[1] Since then, further experience with alcoholic patients has brought out increasing interest in the phenomenological overlap between what are two of our greatest public health problems, the obese patient and the chronic alcoholic.

Surveying the literature, it is evident that there are multiple therapeutic regimens suggested for both with usually discouraging results and a somewhat nihilistic and often hostile approach by the medical profession, especially towards alcoholism.[2-5] However, outside of the medical arena, the major breakthroughs have been made in social innovations where "birds of a feather flock together" for mutual support and therapeutic attempts. The success of Alcoholics Anonymous far out-shadows any known medical onslaught to the problem of alcoholism, and recent organizations such as Weight-Watchers and TOPS (Take Off Pounds Sensibly) are gaining in momentum and success in the social therapy of obesity. Because both over-eating and over-drinking have the same

area of input, *ie,* the mouth, and this is our first social area of relating, it seems that the alcoholic maintains the more regressive, dependent, "toothless" position while the "carboholic" [6] has progressed slightly further, added teeth and thus, has become a somewhat different phenomenon, but with similarities that cannot be ignored.

From the medical-pathological vantage point, both obesity and alcoholism have greater morbidity and higher mortality, but from a sociological point, they are handled quite differently. Alcoholism has recently been seen as a "disease" rather than from the traditional viewpoint as criminal or immoral behavior. However, neither is properly dealt with as a disease entity, but rather may be more clearly seen and appreciated as a manifestation of a behavioral deficit.[7] By this is meant that the alcoholic, like the "carboholic" manifests a circumscribed number of behavior patterns available and uses these to the exclusion of alternatives, not because of weakness of character or immorality but because of a lack of suitable and adaptive behavior patterns. The alcoholic uses drinking behavior because he has no other methods to use in social or tense situations. The same is true of the obese patient who uses food in lieu of other social relationships to deal with loneliness, stress, frustration, or the entire gamut of emotionally charged situations. They eat or drink because they have no other behaviors available to utilize in place of these repetitious and highly cathectic, reliable behavioral forms.

At one level, the over-eater is more advanced, using teeth (aggressive behavior) while the alcoholic uses a less advanced "toothless" oral behavior, both trying to fill some emotional void or need which they cannot seem to fulfill in alternative, more adaptive, less self-destructive manners. In a study of obese patients, it was found that eating behavior occurred continuously through the day, thereby taking up a good deal of behavioral time and excluding the possibility of using or learning alternative and incompatible behaviors which could compete with eating behaviors.[8] The same thing is true of alcoholics, *ie,* the chronic alcoholic is one whose drinking behavior is so pervasive and pre-potent that it precludes other more adaptive behaviors and thereby causes much time and effort to be concentrated on imbibing rather than learning and utilizing newer and more adaptive non-alcoholic behaviors. From a behavioral point of view, it was consistently shown that group therapy and group discussions for obese patients were easily used as methods to bring together people who could talk about food, and feeding behavior, in place of actually engaging in eating. Then, through successive approximations, new and gratifying social behaviors could be elaborated upon, eliminating the need for overt eating behaviors.

It seems obvious that the support and long-term therapy of our own anti-obesity clinic milieu allowed for long-term therapy and behavioral change. The crux of the therapeutic regimen was that the patient was not treated for a month, or some other short-term program, but rather a more rational long-term group supportive gestalt was established and maintained. When the clinic or group contact ended, there was a regression to the previous level of functioning by some, *ie,* a return to the eating behavior and a return to the previous non-adaptive obesity-oriented behavior. However, such long-term, open-ended groups as Weight-Watchers and TOPS offer essentially the most rational method of dealing with this rampant sociological problem. The same can be said of Alcoholics Anonymous, a non-medical, sociological, long-term organization which offers an opportunity for learning new behaviors which compete with the previous self-destructive oral alcoholic behaviors (as is so with Synanon for drug addicts, etc.). Thus, we can move from the problem of obesity with its variety of causes and precipitating factors into the problem of its toothless cousin, alcoholism.

It seems that if we are to understand alcoholism (phenomenologically), we must move from our traditional medical-pathological viewpoint which encourages us to view the alcoholic as being one who drinks, has cirrhosis, portal hypertension, etc., into the more realistic descriptive realm of a social setting where an obese person is not one who eats "too much" but one who eats one meal a day all day long, thus excluding other possible behaviors in a social context. Also we find the alcoholics a medical, social dilemma which does not seem to have an obvious adaptive alternative. It seems that the medical-pathological gestalt has not arrived at the answer point and that a new broader viewpoint is desperately needed. Thus, one must propose a social, behavioral, phenomenological point of view to be of the utmost importance.

Thus, by implication, Alcoholics Anonymous as a sociological force provides an arena for the learning, acquisition, and reinforcement of new social behaviors.[9] In referring a patient to Alcoholics

Anonymous, there are a number of tactical problems which must be dealt with more effectively. The first is a doctor-patient relationship which allows for a referral to Alcoholics Anonymous. As most physicians know, Alcoholics Anonymous is not medically or psychiatrically oriented so that the physician is making a referral outside of the medical system. Because of this, many doctors frequently make the referral as a "last ditch" move without helping the patient to gain and maintain the motivation to seek the help available. A much more useful method would be for a physician who has an alcoholic patient population to become known to and known by the local Alcoholics Anonymous chapter. This way, the patient, who must first admit that he is indeed an alcoholic, can be contacted by an Alcoholics Anonymous representative who acts as a systems liaison between the medical system and the social Alcoholics Anonymous system.[9] After the physician has formed a satisfactory liaison with Alcoholics Anonymous, the next problem becomes more amenable to resolution. Oftentimes, alcoholics will insist that they have been through the Alcoholics Anonymous route and it doesn't work. While there may be some negative transference or some reality factors operating, this is usually best dealt with as a resistance to therapy. The patient may also be hearing the physician rejecting him (a frequent occurrence with alcoholics) and it is important that it be made clear that Alcoholics Anonymous is an adjunctive service to the doctor-patient relationship. Operating in this paradigm is the often encountered, regressive desire or fantasy that the doctor-patient one-to-one relationship will magically resolve the patient's inner turmoil and satisfy his basic oral dependency needs. Through Alcoholics Anonymous or other goal-oriented group programs, this magical quest may be dealt with through the acquisition of new social group behaviors.

At this point, it may be of great interest to introduce some experimental work which substantiates the group therapy approach to alcoholism. Witkin, et al,[10, 11] have shown that each person has a certain cognitive style with some people being very dependent on external cues to moderate their own behavior with very little internal motivational dependence. At the other end of the continuum, are those who operate according to almost exclusively internal cues, tending to negate or deny obvious external cues. In general, the alcoholic, both male and female, has been shown to be more dependent on external feed-back.[10, 11] People whose cognitive style is so externally dependent tend to be seen as passive, dependent, have low self-esteem, etc. While the work on cognitive style does not tell why people will sometimes become alcoholic or sometimes obese or schizophrenic, it does suggest that our therapeutic goals could make better use of the cognitive style in influencing our method of offering new data or alternative behaviors to a wide spectrum of patients. Boiled down, this means that modeling or behaving in front of the patient allows them to mimic or "incorporate" these newer forms of behavior, which is so obvious in the mimicking behavior of children and one of the characteristics of our species.[12] This modeling of behavior also occurs in one-to-one insight-directed therapy, but as one knows, many alcoholics as well as schizophrenics or patients have a great abundance of insight, but no way to put it into overt behavior.

The Alcoholics Anonymous sessions as well as group therapy programs offers this in an acceptable form. One should also keep in mind that the alcoholic behavior is pre-potent, that is, well practiced and readily available. Thus, in a tense situation, the patient can always regress, use a prior behavioral pattern, *eg,* drinking, so that any program aimed at therapy and rehabilitation must take into account the tendency for relapses which are then used in the the therapeutic regimen rather than being the criterion for exclusion from the program. It is almost as if the alcoholic lacks the teeth to cling to the nipple of therapy and we must respond at this dependent level.

Alcoholism is not common in certain people who have a high alcoholic intake. Some eminent specialists stand in opposition to the disease concept of alcoholism. It is not true of other diseases that they can be overcome completely by negative conditioning.

There is no satisfactory or generally accepted definition of alcoholism. Diagnostic and conclusive laboratory, physical, or other signs are lacking. The reasons are not clear why various individuals and groups strive to establish it as a disease. However, such proponents have been known to apply themselves with more zeal than cogency in support of the contention that alcoholism is a disease.

Alcoholism Is NOT a Disease

ERNST SCHMIDHOFER
Director, Professional Education & Training
Professional Education & Training
Clifton T. Perkins State Hospital
Instructor, Department of Psychiatry and the Behavioral Sciences
The Johns Hopkins University School of Medicine

The U.S. Court of Appeals in Richmond, Virginia has said that alcoholism is "now universally accepted medically as a disease."[1] In this paper I should like to offer a dissenting opinion.

From the etymological standpoint alcoholism is a disease. But only because the prefix "dis" means bad and the suffix "ease" means comfort. There seems to be little real justification for calling it a disease although, not uncommonly, there are heavy overtones which imply much more than that.

It is difficult to ascertain whether alcohol causes the disease, or whether it is part of the disease, or both. In any event, it has been pointed out by sociologists that the Italians and the Jews have a high alcoholic intake but a low alcoholic incidence. If alcohol produces a disease or if it is part of a disease, why isn't it present much more often in those two groups? The exposure in them is high, but the frequency is low.

What is the cause of this "disease"? How does it originate? When does it become a disease? If we don't know what causes it or how it originates or when it becomes a disease, how can we call it a disease?

According to McCarthy,[2] the definition of alcoholism in terms of a disease is not recent. He credits the Scottish physician, Dr. Thomas Trotter, with having said in 1804: "In medical language, I consider drunkenness, strictly speaking, a disease; produced by a remote cause, giving birth to actions and movements in a living body, that disorders the functions of health. . . . It is to be remembered that a bodily infirmity is not the only thing to be corrected. The habit of drunkenness is a disease of the mind."

There appears to be a serious weakness inherent in his statement of position. Reference is made to the terminal phrase "disease of the mind." Is it

tenable to attribute the fictitious construct "mind" with the property "disease"? By standard definition, the latter term should be reserved for that which is organic or structural and has substance.

Furthermore, even though Trotter made his pronouncement in 1804 doesn't mean necessarily that it was correct then or now. Surely we would all agree that long before Trotter many things were said by Hippocrates that weren't true then or now either.

McCarthy then cites from the writings of another physician.[3] He excerpts from a monograph on alcoholism which was written in 1854: "And the complex nature of the disease, varying both in cause and effect with every form of constitution and habit, renders it extremely improbable that any such specific will ever be discovered."

The author's reference to the word "specific" is a preventative of further indulgence. Evidently Dr. Day felt sufficiently secure, scientifically, to say it was "extremely improbable" that a specific form of treatment would ever come into being. In terms of degrees of probability, I would venture to say this prediction makes it extremely unlikely that alcoholism is a disease.

Dr. Ruth Fox, research director for the National Council on Alcoholism, has expressed disagreement with the notion that alcoholics are neurotic and rejects the notion that there is a pre-alcoholic personality type. This point is introduced because some people consider alcoholism to be a disease since they view it as a neurosis. In the first place, this notion is not shared by some of our most eminent specialists in the field. Secondly, even if alcoholism were a neurosis, this would not make it a disease because a neurosis is more properly considered to be a disorder.

The distinction is not always made between disease and disorder. Nevertheless, a disease shows itself to be organic in nature, demonstrates abnormality of structure, and evidences anatomic change. On the other hand, a disorder shows itself to be functional in nature, demonstrates abnormality of performance, and evidences physiologic change.

Psychiatric formulations have, at times, been resorted to in an attempt to interpret alcoholism as a disease. According to Isbell,[4] these cannot be proved in the strictly scientific sense. He feels that the best formulation at the present time for the phenomenon of craving is a psychiatric one. It would appear such an interpretation by a scientist of Dr. Isbell's stature, lessens the logicalness of the argument that alcoholism is a disease. It seems that things psychiatric are much more likely to be functional than organic. Surely a craving is better classified relatively as a disorder rather than as a disease.

Upon listening to and reading about alcoholism as it is presented by the champions of the notion that alcoholism is a disease, it is easy to conclude there is supposed to be some sort of defect or shortcoming which separates the alcoholic from all others. But as Isbell points out, after a few days or a week of abstinence the alcoholic is physiologically indistinguishable from his fellows unless he has incurred one of the structural derangements which may be associated with alcoholism.[4]

Diagnostic and Statistical Manual

The American Psychiatric Association's Diagnostic and Statistical Manual of Mental Disorders [5] lists alcoholism under the section on personality disorders and speaks of it as being a disorder without producing clearly defined tangible structural change. Certainly this does not lend strong support to the disease concept, at least from the standpoint of the definitions which have been submitted in this paper.

The president of the International Center for Psychodietetics in Rome, Italy[6] indicates it is lamentable to hear time and again the statement made that alcoholics need help because they are "sick" or "diseased" or "ill." He says, "we have no right to state than an 'alcoholic' is diseased in the same sense as the person suffering from pneumonia or rheumatic fever."

Another distinguished scholar, Esser,[7] feels that the disease concept of alcoholism "must not be extended to all forms of excessive drinking." He declares also that there are those excessive drinkers who imbibe for as long as 30 years without developing loss of control.

Whereas it has been argued that heavy drinkers develop cirrhosis and fatty degeneration of the liver, not every scientist of renown would agree with this. Among those who demur is Dr. E. Jacobsen, a Danish expert.[8]

Dr. Jacobsen does not believe there is a shred of truth in the notion that alcohol poisons the liver. Furthermore, he feels that abstinence, which is so commonly prescribed in liver disorders, does not particularly help restitution of a liver which is already diseased.

Dr. Morris Chafetz, psychiatrist and director

of the Alcoholic Clinic of the Massachusetts General Hospital, who is also special consultant for the National Institute of Mental Health, points out that alcoholism should not be considered a disease. He views it rather as a symptom "of a wide variety of underlying emotional, physiological, and social problems." Furthermore, it is his opinion that "most professionals in the field prefer the view that alcoholism is a symptom analogous to headache or fever." [9]

The human body may be conveniently classified into the following systems: (1) skeletal (2) muscular (3) vascular (4) neural (5) special senses (6) respiratory (7) digestive (8) endocrine (9) reproductive (10) urinary (11) skin.

Of all the diseases known to afflict those 11 body systems, I do not think of a single one which can be overcome completely by negative conditioning, as by means of injecting apomorphine. But alcoholism can. Again, this does not seem to speak for it as being a disease.

O'Halloren states he has given the aversion treatment over 75,000 times in treating a series of 10,000 alcoholics. He reports the following results: "Physicians utilizing this program of management for their alcoholic patients may expect total sobriety ranging from one year to life in more than 60% of those treated." [11]

This investigator indicates he compiled his statistics accurately and carefully over a period of 21 years. Considering the fact that he uses the aversion treatment, the remarkably high incidence which he reports with the use of that method is impressive. It is impressive not only in terms of the good results obtained, but also because the effectiveness of that technic makes it appear unlikely that alcoholism is a disease.

Coming back to all the diseases that are known to afflict the 11 body systems, which ones or which one of them will respond to conditional reflex therapy to the degree that the physician utilizing such a program can expect complete recovery ranging from one year to life in more than 60% of 10,000 of such cases which he treats?

It has been noted that the decision of an alcoholic to stop drinking is often prompted by threats of one sort or another. It may be loss of a job. It may be dissolution of the family. There may be factors which threaten his security. His physical health may become impaired severely. He may lose the respect of his associates.

Many alcoholics will agree to treatment only after the spouse files suit for divorce, or when the employer makes it clear that continued employment depends upon elimination of the drinking problem.

Of all the diseases which are known to afflict the 11 body systems, which ones or which one can be held under control, and like alcoholism, be kept from coming into existence through making any of the decisions or any of the resolutions mentioned in the paragraphs above?

There are ethical, as well as technical reasons, for arguing against the notion that alcoholism is a disease. For one thing, to consider it as a disease tends to foster dependency needlessly, even in those who are tempted to resist this state. For another, this consideration turns the focus of attention away from the cause and, therefore, will almost certainly delay the time that will be required to discover or develop a cure which is suitable and satisfactory.

In her customary scintillating style, the illustrious writer Schmideberg, equates some of the promises of psychiatry with hopes and disillusionment. She points out that the journalese term "sick" was coined in order to evoke sympathy for delinquents. The chief drawback to this is it "glosses over the fundamental issue as to what is wrong with the offender."[12] Almost certainly this very same factor is operative with reference to using the "sick" approach to alcoholics.

Perhaps one of the most unsatisfactory aspects of the concept that alcoholism is a disease is there is no satisfactory or generally accepted definition for the condition of alcoholism. Surely this does not contribute heavily to the justification for considering it to be a disease.

There seems to be general agreement that a disease is characterized in part by gross and/or microscopic pathologic changes. It is an affliction which is organic rather than functional. If alcoholism is a disease, where is the pathology? If alcoholism is a disease, what is the pathology?

It appears the sponsors of the concept that alcoholism is a disease have little more to show than physiological changes such as vasodilation, and a biochemical one resulting from an increase in the blood-alcohol level. These alterations can make alcoholism eligible for consideration as a disorder, but hardly as a disease.

No Pathognomonic Lab Findings

Of all the laboratory studies extant, I do not think of one that has been established to make the determination that alcoholism is a disease. Nor

do I know of any other means whereby this can be done.

Other demonstrable diseases have identifying physical signs and characteristics or other criteria for validating them as being organic maladies, either ante mortem or post-mortem. Is this true for alcoholism? Not insofar as I am aware.

Alcoholism will make a person dizzy and dystaxic. But so will self-induced whirling. Does this make self-induced whirling a disease? If not, why not? The answer to these questions and related ones should make possible a clear and easy and clean-cut distinction between alcoholism as a disease entity, and other disorders which it may resemble. Yet, these answers do not seem to be forthcoming from anyone anywhere.

It does seem strange that of all the people in the world who pronounce alcoholism to be a disease, no one has brought forth facts which confirm this as a verity.

It has been said that a "dry" drunk consists of experiencing the same symptoms as having drunk heavily without actually having imbibed any liquor. What other disease can be reactivated in terms of simulation, in the absence of the item or elements which caused it?

One of the reasons for so much vigor behind the disease concept of alcoholism may be the fear that if this appelative foothold is lost, the alcoholic will be dealt with harshly, rather than treated comfortingly. But surely a shift to the non-disease concept will not induce a gentle therapist to become harsh, any more than adherence to the disease notion will induce a harsh therapist to become gentle.

From the standpoint of probability, efforts to justify alcoholism in terms of a disease, in the absence of good and valid criteria, speak strongly against the likelihood that such indeed is the case.

Because the alcoholic is sick does not prove he has a disease. Motion sickness or drinking too much salt water or eating too many doughnuts can make us sick, too. But that doesn't mean we have a disease.

Many less articulate alcoholics intensely resent the hue and cry that is put up by some of their more vocal brethren. It would appear that some of the latter exploit the disease concept of alcoholism not so much from the standpoint of getting sympathy as they do for making a bid for attention. There is evidence that some do this to provide themselves with an acceptable social excuse for their own ineptness or inadequacy. These traits are then ascribed to all alcoholics, including those who neither want them nor have them.

To speak of alcoholism as being a disease, or to say "unquestionably the alcoholic is a sick man", betokens certain precious values. If a man is sick, then he is deserving of pity. He is also eligible for varying quantities of sympathy. Furthermore, there may be coming to him gratuities and financial support from various sources and organizations.

For him to be sick creates a good image in the eyes of the public, and someone is likely to lend him a helping hand. Legislation may be enacted and research monies may be granted for the construction of hospitals and sanitaria dedicated to his care and protection.

Another view of alcoholism shows it to be not so much a disease as a problem. One could even say it is no more a disease than are other episodic disorders such as, check forging, kleptomania, pyromania, and tantrum throwing.

On occasion, alcoholism is spoken of as though it were an addiction. And there appears to be some evidence that it is an addiction. However, this does not give much strength to the disease concept. Any number of the following might also come under the category of addiction. I include now cigarette smoking, competing, complaining, overworking, speeding, succeeding, swindling, taking sedatives, using laxatives, viewing the television, and vying with slot machines. But are these diseases?

Daytop Drug Addiction Concept

The acronym "Daytop" stands for drug addiction treatment of probationists.[13] This group consists of self-reforming drug addicts. They contend that drug addicts do not suffer from any exotic form of disease.

The group numbers more than 100 members ranging in age from 18 to 45. These men and women see drug addiction as an outstanding example of one consequence which can result from attempts to dodge life's basic commitments.

The people at camp Daytop consider themselves as having been more skillful dodgers than most and to have succeeded more dramatically. They feel they have not assumed their rightful amount of individual responsibility.

Finally, the authorities who closely supervise Daytop are not highly enthusiastic in response to widely-voiced exhortations for cures with some

miracle drug. Their unresponsiveness to such excited overtures stems from the fact that, like their charges, they do not consider drug addiction to be a disease.

Some psychoanalysts claim there is a bond of union between alcoholism and certain other conditions. But rarely does anyone speak of those states as being diseases. They include: ceaseless talkers, excessive coffee drinkers, those who must continually dominate every situation, those who go on dress-buying sprees, some leaders of some clubs, over-eaters, poker players, race-track addicts, and some reformers of some societies.

It has been said that alcoholism is a disease because it is stereotyped, repetitive, maladaptive, determined, and poor in self-prediction. But such characteristics apply also to a number of diverse conditions such as, bed wetting, belching, cigarette smoking, cursing, dreaming, fighting, gum chewing, hair twisting, horn honking, indebtedness, insomnia, littering, philandering, prostituting, sleep walking, spitting, throat clearing, and thumb sucking.

Would it be proper to call alcoholism a problem rather than a disease? The answer may be posited in the affirmative because it is a problem from the standpoints of definition, diagnosis, epidemiology, etiology, family, management, recovery, society, and treatment.

Those who might find unsatisfactory the word "problem" would perhaps prefer to substitute affliction, condition, disorder, malady or state. I would guess the dissentients are among those who press hardest for having alcoholism thought of as a disease. Such a stand might be taken because of the comprehensive appreciation these people have for the semantic overtones generated in differing directions by such opposite words as "problem" and "disease."

It is acknowledged one cannot say precisely what alcoholism is in the framework of our present discussion. But this doesn't mean one shouldn't argue against what it isn't. Failure to do so would contribute to calling off a search for the actual cause. In this sense disagreement is expressed with the argument that one should not disparage a set of procedures if he cannot offer a substitute plan. Perhaps it is better to do nothing than do something wrong. *Primum non nocere.*

At the present time, the claimant majority is holding sway. But there seems to be a growing reticent minority which reasons that alcoholism can be explained much more accurately in terms of learning, overlearning, relearning, and unlearning.

It has been pointed out earlier that alcoholism may lead to disease, in the view of some people. It has also been pointed out that this does not prove alcoholism itself is a disease. Perhaps the indication is timely for a brief tautology on why alcoholism should not be classified as a disease.

When children engage in drinking contests, they may suffer from water intoxication and even death. Because they drink too much water, does this mean hyperhydration is a disease?

Overeating may lead to diabetes, heart trouble, obesity, and vascular hypertension. Because omniphages eat too much food, does this mean they must have a disease?

Consuming alcohol to excess leads to a state of insobriety. Devouring food to excess leads to a state of satiety.

Each of those two states is a condition which is temporary for a particular instance. Each is done repetitively. Each can be indicative of varying kinds of problems. Each is deleterious in the long run. Each is engaged in by all manner of men and women. Each can be started most any time. Each can be terminated most any time. And each can be tolerated up to a point. From these standpoints it does not seem reasonable that alcoholism should be classified as a disease and overeating as a habit.

One might feel that chemistry determinations of the blood could be helpful. But are they? I am not aware of any such studies, nor of any others whereby it is possible to establish as a fact that alcoholism is a disease.

(1) Blood chemistry findings do not distinguish between a teetotaler and an alcoholic who has not been drinking for quite some time. (2) The finding of alcohol in the blood enables the investigator to say the subject had been drinking recently. But he cannot say whether or not the person is a "non-alcoholic" imbiber of intoxicants or an "alcoholic" in the present sense of the word. (3) The absence of alcohol in the blood does not prove that the man is not a chronic alcoholic. He may have been abstinent for a sufficient length of time before the blood was drawn and examined.

Once again we are confronted by the issue which keeps recurring throughout this paper. What are the criteria being used by those who aver that alcoholism is a disease?

Just how does one go about establishing that alcoholism is a disease? Animal inoculation? Biopsy? Bone marrow aspiration? Cerebrospinal

fluid? Frozen sections? Gross findings? Microscopic investigation? Physical examination? Sputum determinations? Tissue cultures? Urine? X-ray studies? Just which criteria are pathognomonic and obtained from just which tests?

Just what manner of disease is it that allows for the offending agent to be reintroduced in the same quantity which originally incapacitated the individual (from an alcoholic debauch) but some years later no longer does so (after he has become a confirmed heavy drinker)?

Perhaps there are immune bodies which can account for this. One might say the alcoholic developed an immunity against a recurrence of the disease. However, as I understand it, alcohol is not known to be antigenic. To my knowledge, no one has ever demonstrated any immune body against the offending agent in an alcoholic.

Just what other disease blights such a relatively small minority when the active ingredient is consumed by an ever-increasing majority?

It would seem to be expecting much of the diagnostic and intellectual sensibilities of seasoned scientists to ask them to conclude that alcoholism is a disease which, out of 20 persons, affects one individual who drinks a certain amount of liquor, but which malady is not reproduced in the 19 others who drink an equivalent amount of the disease-producing potion.

Is there any other disease which can be turned on and off, and which is under an equivalent amount of voluntary control?

From the standpoint of turning it on and turning it off, alcoholism is no more a disease than is nailbiting. In matter of fact, the latter at least has gross evidences of structural change, both manifest and unfailing.

In successful instances, alcoholism can be and is handled satisfactorily without professional help of any kind whatsoever. Furthermore, what other disease can be held at bay so absolutely and so positively by simply climbing on the water wagon?

At this point, it would seem safe to say that alcoholism may be considered more appropriately as a condition whose primary state is not a disease and which does not begin as a disease but may lead, in time, to disease processes in the heart, the kidneys, the liver, and elsewhere.

These criteria do not lead inevitably or incontrovertibly to the conclusion that the primary state of alcoholism is a disease, or that it began as a disease. For instance, a person can go skiing (the primary state) and end up with a leg fracture. Does this mean that skiing is a disease or that it began as a disease? A person can go horseback riding and end up with a ruptured spleen. Does this mean that horseback riding is a disease or that it began as a disease? A person can go swimming and end up drowning. Does this mean that swimming is a disease or that it began as a disease?

Such considerations would perhaps allow more properly for the interpretation that alcoholism is a condition and not a disease. This is perhaps a more accurate portrayal and worthy of unimpassioned consideration partly because "condition" suggests something which is temporary and subject to control. Additionally, it indicates generally a more favorable outlook than is true for "disease."

There seems to be little difficulty in considering cancer, diabetes, heart trouble, pneumonitis, tuberculosis, and typhoid fever as being bona fide diseases. Why is there difficulty in trying to establish alcoholism as a disease? Why is there discussion about it? Why is there argument regarding it? Why are there diverging comments written about it?

Not Looking In The Right Places

Perhaps it will prove to be true that the "disease" alcoholism is not so much descriptive of an organic change, as it is representative of a chimeric idea.

And it may come to pass that up to now the search for its existence has been unrewarding because we have not been looking for it in the right places. The suggestion is that this "disease" is present not as an entity in the bodies of those who are alcoholic, but rather, as a concept in the brains of those who have labeled them so.

your medical faculty at work

by John Sargeant
Executive Secretary

The Council at its January 16, 1969, meeting took the following actions:

1. Adopted the minutes of previous meetings, as well as Executive Committee sessions.
2. Waived 1969 dues for a physician who is ill, at the request of the component society involved and in accordance with Article III, Section 7, of the Faculty Bylaws.
3. Ratified various physicians' defense cases.
4. Heard of a settlement of a case wherein the judge had directed a verdict in favor of the physician.
5. Adopted the proposed 1969 budget.
6. Authorized submission of names to the Blue Shield Board for (1) nomination for election to the Board and (2) appointment to the Medical Relations Committee and Reference and Appeals Committee. These were:

Blue Shield Board of Trustees: (three-year term)

Terms expiring of:

William Carl Ebeling, MD, Baltimore	Internal Medicine
Gerald A. Galvin, MD, Baltimore	Gynecologist
Arthur T. Keefe, Jr., MD, Chestertown	General Surgeon

(All recommended for reappointment)

Others presently serving on the Board:

J. Sheldon Eastland, MD, President, Baltimore	Internal Medicine
Charles F. O'Donnell, MD, Vice-President, Towson	General Practice
Edgar T. Campbell, MD, Hagerstown	Radiologist
George D. Edwards, MD, Towson	Ophthalmologist
Claude D. Hill, MD, Baltimore	Obstetrician
William G. Speed, III, MD, Baltimore	Internal Medicine

Medical Relations Committee: (one-year term)

Consists of Board of Trustees, plus 3 additional physicians who are, at the present time:

John S. Haines, MD, Baltimore	Urologist

Recommendation that he be replaced by:

Thurston Ray Adams, MD, Baltimore	General Surgeon
W. Bradley King, MD, Baltimore	Pathology
Paul A. Mullan, MD, Baltimore	Pediatrician

(Both recommended for reappointment)

Reference and Appeals Committee: (one-year term)

W. Bowdoin Davis, MD, Baltimore	Plastic Surgery
Albert H. Dudley, MD, Baltimore	Obstetrics/Gynecology
J. T. H. Johnson, III, MD, Baltimore	Orthopedics
Nicholas Mallis, MD, Baltimore	Urology

(Continued next page)

W. Kenneth Mansfield, MD, Baltimore	Obstetrics/Gynecology
B. Martin Middleton, MD, Baltimore	Surgeon
Granville H. Richards, Jr., MD, Cecil County	General Practice
Henry H. Startzman, Jr., MD, Baltimore	Radiology
Wilfred H. Townshend, MD, Baltimore	Internal Medicine
(All recommended for reappointment)	
A. Talbot Brice, MD, Frederick County	General Practice
Recommendation that he be replaced by:	
Leon W. Berube, MD, St. Mary's County	General Practice
Harold C. Dix, MD, Baltimore	Ophthalmology
Recommendation that he be replaced by:	
Gregory John Sophocleus, MD, Towson	Ophthalmology
William B. Holden, MD, Baltimore	Psychiatry
Recommendation that he be replaced by:	
Jacob C. Handelsman, MD, Baltimore	General Surgeon
Harry M. Robinson, Jr., MD, Baltimore	Dermatology
Recommendation that he be replaced by:	
John F. Strahan, MD, Baltimore	Dermatology

7. Authorized submission of names of nominees for possible election to the Blue Cross Board of Trustees as follows:

Terms expiring of:	
B. Martin Middleton, MD, Baltimore	General Surgeon
J. Arthur Weinberg, MD, Baltimore	General Surgeon
(Both recommended for reappointment)	
Others serving on Board (physicians only):	
J. Tyler Baker, MD, Easton	Obstetrician
William D. Lynn, MD, Baltimore	General Surgeon
Richard A. Young, MD, Hagerstown	Pediatrician

8. Heard a progress report regarding the proposed Multiphasic Screening Project and adopted the following motion:

   "The Council approves of Multiphasic Screening as outlined and directs its Ad Hoc Committee to proceed with its investigations, keeping this Council fully informed of its findings and recommendations."

9. Voted that the Subcommittee on Chronic Diseases be requested to prepare a report for Council outlining the care of hospitalized Tbc patients in Maryland which would include the economic, ancillary, consultant, familial factors involved in the care rendered to such patients and make a thorough investigation as to the type and quality of care being rendered to those same patients in tuberculosis hospitals in Maryland.

   At the end of the Council meeting, the Council reconsidered this motion and adopted one that would permit the President to name an ad hoc committee to conduct this investigation, rather than referring it to the Subcommittee on Chronic Diseases.

10. Deferred endorsement of a State Health Department proposed Glaucoma Screening Project and requested a definitive answer from the Maryland Ophthalmological Society in this connection. It also authorized the Executive Committee to endorse such a project, if it deemed this advisable, after receipt of this definitive answer from the ophthalmological group. It is to be understood, however, that such endorsement would cover only the research aspects of the proposal; and not that section devoted to the establishment of mass screening projects of this nature throughout the State through the State Health Department.

11. Approved a recommendation of the Medical Economics Committee that it endorse a proposed rate increase of 19.4% in the professional liability rates offered Faculty members through the St. Paul Professional Liability program; and an increase of 25% in the basic limit rates. This will still leave the Faculty's program under national rates by 34%.

12. Heard information with respect to amounts paid to hospital educational funds by Blue Shield; and elected to ask for clarification of certain purposes for which these funds were being used by hospitals.

13. Heard a report on the 1969 General Assembly and bills affecting the medical profession.

14. Voted to table the following two motions of the Committee on Emotional Health:

    (a) All General Hospitals in Maryland should be notified again of the endorsement of the Faculty policy adopted in 1965, and offers its support for any effort on their part to develop psychiatric inpatient beds.

    1965 policy was:

    The Medical and Chirurgical Faculty of Maryland heartily supports the inclusion of psychiatric services, both inpatient and outpatient, in all general hospitals in the State of Maryland.

    (b) The Council submit a resolution to the Governor and General Assembly endorsing the request of the Department of Mental Hygiene for this item (a budgetary request of $400,000) to be included in the State Budget for the purpose of establishing a Drug Abuse Center.
    The Faculty's House of Delegates endorsed the concept of such a center at its Annual Meeting, 1968.

15. Acknowledged with thanks the receipt of $500 to be placed in the Laughlin Award Fund. The gift was made by Henry P. Laughlin, MD.

16. Adopted a recommendation of the Pharmacy Liaison Subcommittee and the Mediation Committee as follows:

    The Medical and Chirurgical Faculty of the State of Maryland opposes direct telephone lines between a physician and a pharmacist.

The Maryland Pharmaceutical Association and the C & P Telephone Company will be notified of this action.

17. Adopted the following in connection with Maryland's Medicaid program:

    The Executive Committee is authorized to appoint such Faculty members or employees as it feels necessary to properly represent the Faculty in any investigations regarding or involving physicians in the State's Medicaid program.

After adoption of this motion, the following was approved:

    If a satisfactory agreement can be reached by the Faculty and the State, that the Blue Shield Board be asked to administer the program, after it has reviewed it and is satisfied that such a program can be adequately administered.

The Council then suggested the following guidelines be used in any investigations as approved in the first motion adopted on this subject:

1. The basis for payment be the Physician's Usual, Customary, and Reasonable fee for all inpatient and outpatient services rendered Medicaid recipients by private physicians.

(Continued next page)

2. Any inpatient or outpatient care rendered Medicaid recipients by house staff, teaching staff, full or part-time salaried physicians, Fellows or any other term used for those physicians who are paid salaries, per diems, etc., by hospitals, foundations, or any other term, *where an employee relationship exists,* shall not be considered as physician's services for purposes of payment, but shall be included in hospital costs as calculated in the average per diem hospital cost of each hospital or institution.

3. Any outpatient services provided recipients at hospital OPD under Medicaid shall be billed by the hospital rendering service and paid by Blue Shield on the basis of Usual, Customary, and Reasonable fee, for the area involved. However, such payment shall then be deducted from fees paid that institution by Blue Cross or that group paying for the Medicaid patient's care so as to avoid duplication of payment and discourage overutilization by the recipients who sometimes tend to wish excess care or tend to "doctor shop" or both. Where such professional services are rendered by this mechanism, an adequate summary shall be kept so that statistical data can be provided for comparison as to the cost of care rendered in this setting as compared to a private physician's office setting.

4. That any premium per recipient be computed as closely as is humanly possible to permit payment to physicians of their Usual, Customary, and Reasonable fee and shall be based on a per month, per recipient, basis.

5. It is to be understood that, should best estimates fall short of actual costs for fiscal 1970, the physicians of Maryland will underwrite the program by accepting a reduction of their Usual, Customary, and Reasonable fee to a percentage that will allow the program to function within the funds received through the rate charged.

6. It is also understood that this is for the fiscal year 1970 only; and that activity for fiscal 1971 is renegotiable.

7. If any overage occurs in the program, this will be rebated to the State.

8. Every attempt shall be made to meet with other professional groups for the purpose of assisting them in their negotiations with the State, in all areas including advice as to the carrier which would be best suited to assist them in the administration of the program; and determining their premium structure.

9. Premiums will be calculated on a one-year basis, payable per person, per month; with drops adjusted on a quarterly basis; and with starts to be effective, retroactive to the first of the month in which they are authorized as a Medicaid recipient.

10. Policing of the physician portion of the Medicaid program will be handled through already existing mechanisms of the Faculty and the Commission on Medical Discipline. Where fraud exists, action shall be initiated by the State's Attorney's office both for actions against physicians, as well as those patients who might practice fraud in the program.

The Executive Committee met on February 7, 1969, and took the following actions:

1. Adopted a two-step rent increase for the State Board of Medical Examiners.

2. Acceded to a request from the Baltimore City Medical Society to permit that group's monthly meetings to be held on the first Thursday of each month. This necessitates a change in the scheduling of Executive Committee and Council meetings for 1970.

3. Visited with representatives of the State Health Department to discuss (a) mechanisms for handling complaints and investigations involving the Medicaid program (b) received statistical data in connection with the Medicaid program and requested additional information as soon as it is available (c) heard that no final decision has been made in connection with the purchase of Part B, Medicare, for Medicaid recipients who are eligible for such Part B, Medicare (d) agreed to work towards a system of peer review as quickly as possible and (e) discussed briefly the proposed formulary for use in the Medicaid program, reaffirming the Faculty's endorsement of such a system.

4. Authorized preparation of a press release containing factual data in connection with the Medicaid program, specifically insofar as 3 (b) above was concerned.

5. Heard that the Advisory Council on Mental Hygiene had decided to continue its policy of not meeting until its role and functions could be clarified; and heard that it felt this may change with the new Governor.

6. Agreed to address a letter to the Social Security Administration at Woodlawn in connection with its medical policies at the Employee Health Service; deciding that such will be referred to the Faculty's House of Delegates for action if a satisfactory reply is not received.

7. Decided that those committees which did not have recommendations for the House of Delegates need not be included in the annual reports to the House if they are not ready in sufficient time for the printer's deadline. These reports would then be made to the Semiannual Session of the House.

8. Agreed to submit the following names for the appointments shown, all made by the Governor:

   Occupational Disease Board: J. Sheldon Eastland, MD, (reappointment)
   Advisory Board on Hospital Licensure: Edmond J. McDonnell, MD, (reappointment)
   Advisory Board on Hospital Construction: Benedict Skitarelic, MD, (reappointment)
   Board of Physical Therapy Examiners: W. Grafton Hersperger, MD (to fill an unexpired term of Wetherbee Fort, MD, deceased)

9. Deferred action on submission of names of Physical Therapists for appointment by the Governor to the Board of Physical Therapy Examiners, until the March Executive Committee meeting.

10. Approved submission of the name of Harold P. Biehl, Jr., MD, for possible submission to and appointment by the Governor to the Maryland Occupational Health and Safety Advisory Board.

11. Approved meeting jointly with the Maryland Nursing Home Association Executive Committee.

12. Agreed to meet "on call" with the Maryland Hospital Council's Executive Committee.

13. Deferred action on approval of a Glaucoma Screening Project at the Social Security Administration until it could determine the medical policies at that organization (see item #6).

14. Stated it had no objection to a data gathering request from the Regional Medical Program which would ask physicians to cooperate in this area.

15. Approved the submission of one name for possible appointment to an AMA Council or Committee; and declined to do so on another name because he was neither a member of the Faculty nor the AMA.

16. Heard and discussed various legislative matters before the General Assembly.

(Continued next page)

17. Declined the use of Osler Hall for a talk on tobacco which would have been presented to pupils of School #49.

18. Declined to participate in an AMA-ERF fund raising appeal suggested by the AMA.

19. Designated John F. Schaefer, MD, to serve on an Advisory Committee of the Maryland, DC, Delaware Hospital Association to Develop Suggested Guidelines and Principles for Pharmaceutical Services.

20. Heard a request from the Maryland Society of Anesthesiologists for a representative of that group on the Blue Shield Board. Advised that group that it is impossible to have a representative of every specialty organization on the Blue Shield Board, and that in cases such as this, consultants are named. The Anesthesiology group already has a designated consultant to the Board.

21. Heard that the Workmen's Compensation Commission has declined to adopt the concept of Usual, Customary, and Reasonable Fees; and that a schedule is being developed and the Faculty will be advised when it is ready and a hearing date is set.

22. Approved a form submitted by the Maryland Medical Assistance Advisory Committee for use in transfer of patients between hospitals and extended care facilities.

DOUGLAS G. CARROLL, MD, EDITOR

rehabilitation notes

Rehabilitation of Patients with Rheumatoid Arthritis

Rehabilitation of the patient with rheumatoid arthritis requires a comprehensive and long-term approach, preferably by a single physician. Many badly crippled patients can be helped by rehabilitation techniques, but rarely dramatically. The study of late cases suggests that many deformities could be prevented or significantly ameliorated if treatment and preventive measures had been started and continued at an earlier stage in the disease. Motivation plays a major role in the final outcome.

* * * * *

Definition

Rheumatoid arthritis is a chronic inflammatory disease of unknown origin which is systemic in nature and characterized by the manner in which it involves joints.[1-5] It runs a prolonged intermittent course, resulting in severe disability in approximately 30% of the patients. The principal cause of disability is the painful joint and the contracture and atrophy of contiguous muscles. Less frequently there is severe osteoporosis with lysis of the involved joints.

Psychiatric Aspects

Patients with rheumatoid arthritis who come to a municipal hospital are a highly selected group of older people with severe deformities and few social resources. The largest number of acute initial cases of rheumatoid arthritis occur in young females. At this time of life they are either self-supporting or supported by parents or husband. Consequently, they are seen by private doctors in private hospitals as long as they, or their relatives, can pay for private medical care.

The older patients with deforming rheumatoid arthritis are almost always victims of a prolonged, painful, gradually-limiting disease. Consequently, nearly all of them are deeply depressed, have given up hope and are frequently attached to hospital life. They are often fearful and confused. They receive information about arthritis from friends, from advertisements in magazines, and from popular medical articles. They may shift from one doctor to another, try new remedies, or move to a new part of the country in an attempt to obtain relief.

Evaluation and Treatment

Since this disease is frequently intermittent and of long duration, treatment must be carried on for long periods of time, possibly the patient's entire life. It is, therefore, important to evaluate the patient carefully when the initial diagnosis is made. Investigation of the activity and extent

of the arthritis, evaluation of functional capacity by the use of muscle tests, joint range of motion and the activities of daily living (ADL) are essential. In addition, a knowledge of the patient's psychological background and outlook, his family and social situation, and his vocational potentialities is necessary in planning management. For these reasons it is helpful to hospitalize the patient for a period of one month to six weeks early in the disease in order to perform the evaluation and determine the mode of management, as well as to educate the patient about his disease.

As for treatment, a number of drugs have proved to be of help in relieving pain in rheumatoid arthritis. Their use will not be discussed here, but any drug or modality which relieves pain promotes the maintainence of range of motion and muscle strength.

Rehabilitation

The purpose of rehabilitation in rheumatoid arthritis is 1) to relieve pain, 2) to maintain muscle strength and range of motion, and 3) to compensate for loss of range of motion and muscle strength late in the disease if severe deformities have occurred.

Relief of Pain: In addition to the use of drugs, there are several methods which are helpful in the alleviation of pain during the acute stage of rheumatoid arthritis.

Immobilization: During the acute stage, bed rest is most helpful in relieving pain. Individual joints may be immobilized by the use of splints.

Heat: Almost any type of heat will give temporary relief of pain in involved joints. When the pain is in the hands or feet the use of paraffin baths once or twice daily is often of significant value. Moist-air cabinets, Hubbard tanks, or hot baths are helpful where many joints are painful.

Maintainance of Range of Motion and Muscular Strength:

Positioning in bed: The bed should have a moderately hard mattress. A bed board is usually indicated. A soft mattress results in adduction and internal rotation of the shoulders in the supine position. Ulnar deviation of the wrists and fingers is favored when the patient's body sinks into the mattress. Pillows under the head increase the dorsal kyphosis. Pillows under the knees promote hip and knee flexion contractures. The feet should be protected from the weight of the sheets by a foot board.

Poor positioning in bed can cause irreparable damage in as little as two weeks time in some patients. Lying on the stomach several hours daily helps to prevent hip and knee flexion contractures.

Range of Motion: The patient must be taught to treat himself. Interest in this program wanes several months after the patient leaves the hospital unless rapport is established and maintained. A complete explanation of the common deformities and how they may be prevented is essential. Directions to the patient must be simple, and only the most important joints should be worked with. If a joint can be taken through the full range of motion twice daily, range of motion can be maintained.

Selective Muscle Strengthening: The muscle atrophy which is part of the disease is made worse by disuse. Efforts, therefore, should be made to maintain muscular strength in muscles crossing the most important joints. The patient should understand why he is performing the specific exercises, how often they should be performed, and exactly how to do them. The program should be performed by the patient under the direction of the physical therapist until carried out correctly. A written program should be made out individually for each patient.

Particular care should be taken to maintain motion and strength in the following joints.

Knees—Flexion and Extension: These are probably the most important joints in the body from the point of view of function in the patient with rheumatoid arthritis. Knee flexion contracture is the most common reason for forcing the patient to bed. Once patients are forced into bed, contractures of the upper extremities follow rapidly.[6]

Hips—Flexion and Extension.

Shoulders—Full elevation and abduction of the arm.

Forearms—Supination.

Wrists—Dorsiflexion, radial abduction.

Thumbs—Abduction (Abductor policies brevis) and extension.

Fingers—Index finger abduction (First dorsal interosseus).

Flexion and extension at metacarpal—phalangeal joints.[7]

Use of Splints: Splints may be used to give complete immobilization of an acutely inflammed joint. This is an effective way to relieve the swelling and pain. The fear that complete immobilization would inevitably lead to contracture has been definitely disproved.[8-10] Acutely inflamed joints may be completely immobilized in casts for as long as a month with the expectation that the joint will regain its function if appropriately treated with physical therapeutic methods on removal from the cast.

In subacute joint activity, splints which are removable several times daily or worn only at night may be effective in promoting immobilization.

Splints may also be used to prevent the gradual drifting of joints into poor position. For this purpose splints may be worn at night.

For complete immobilization, an unlined plaster cast is believed to give the maximum degree of immobilization. New plastic splints have greatly increased the strength and decreased the weight of splints so that they may be worn for months without wearing out.[11]

Serial knee splints increase range of motion in the knees, but the knees will contract into flexion again unless the patient uses the legs for walking. Dynamic or lively hand splints are effective in increasing range of motion in the fingers—if used before ankylosis or joint destruction has occurred.

Surgery in Arthritis: A large number of surgeons have become interested in rheumatoid arthritis and are rapidly gaining experience under a wide variety of circumstances in many areas of the body.[12, 13] Before undertaking reconstructive surgery in rheumatoid arthritis, it is necessary not only to know the condition of the bones, joints and muscles, but also the motivation, emotional make-up, and vocation of the patient. Even under the best conditions, recurrences of the disease may make well-performed surgical procedures useless.

The general indications for surgery are deformities which produce discomfort, loss of function, or a bad cosmetic appearance, and which cannot be corrected by non-surgical means.

Self-Help Devices: In patients with severe contractures of the back, arms or legs, a number of devices may be used which allow performance of the tasks of daily living when physical or surgical methods are not appropriate or have failed. Patients with severely contracted hips may be helped by a wheelchair. For patients who are unable to bend forward to reach the foot, gadgets to help with putting on stockings and shoes may be helpful. Patients with hip contractures may be helped by a raised toilet seat and by chairs with a slanting seat.[14]

Results of Treatment in Patients Treated at Baltimore City Hospitals

Diagnostic Group 1:

Twenty-seven patients who had rheumatoid arthritis without associated diseases were treated for six months or more. At the end of the treatment, these patients were arranged in rank order dependent on the degree of improvement they had shown in activities of daily living.

The final ranking was then compared with the ranking of a number of measurements made at initial evaluation. The Spearman Rank Correlation Coefficient (r_s) of final ranking with age when first seen was .46; the r_s of duration of illness with final ranking was .32; the r_s for initial MSCL score with final ranking was —.16; the r_s for initial ADL score with final ranking was .68; the r_s for duration of treatment with final rank was .13.

This analysis suggests that the ADL score at initial observation is the most important measurement in predicting how much a patient will improve under treatment. The higher the initial ADL score, the more likely the patient will be to show improvement in the ADL score while under treatment. The patient's age, the duration of the disease, the duration of treatment and the initial MSCL score were of decreasing importance in predicting the outcome of treatment.

Diagnostic Groups 1 and 2—Combined (Table 1 *see page 75* **):**

Of the 29 patients in this combined group, one had high blood pressure and the other mild diabetes. Table I shows that five reached full independence, two reached an ADL score of 90 to 99, and five improved slightly. Nine did not improve and eight deteriorated or died. The num-

bers are small but agree with the findings of the Spearman Rank Correlation Coefficient analysis that there is no initial finding of outstanding help in predicting whether the patient will or will not improve significantly in ADL score.

Diagnostic Group 3:

The 16 patients in this group had associated manifested disease other than rheumatoid arthritis. Five had heart disease, five had lung disease, eleven had neurological or psychiatric problems. One had osteomyelitis of the spine. This group is in no way comparable to Groups 1 and 2, since rheumatoid arthritis was often only an incidental finding. (The importance of separating patients with multiple diseases from those with only one disease has been emphasized.) Of these 16 patients, two reached full independence, two reached an ADL score of 90 to 99, one improved slightly, nine did not improve, and two deteriorated or died.

——O——

This is the last of eleven essays on initial evaluation and prediction of performance of patients criteria for the selection of patients who may be expected to benefit from rehabilitation techniques and to judge later whether these predictions have been realized. The last two articles have illustrated the use of different statistical methods in two specific disease entities. The purpose of this series is to bring more precise methods of measurement into the field of physical rehabilitation.

Preludin®
phenmetrazine hydrochloride

Preludin is indicated only as an anorexigenic agent in the treatment of obesity. It may be used in simple obesity and in obesity complicated by diabetes, moderate hypertension (see Precautions), or pregnancy (see Warning).
Contraindications: Severe coronary artery disease, hyperthyroidism, severe hypertension, nervous instability, and agitated prepsychotic states. Do not use with other CNS stimulants, including MAO inhibitors.
Warning: Do not use during the first trimester of pregnancy unless potential benefits outweigh possible risks. There have been clinical reports of congenital malformation, but causal relationship has not been proved. Animal teratogenic studies have been inconclusive.
Precautions: Use with caution in moderate hypertension and cardiac decompensation. Cases involving abuse of or dependence on phenmetrazine hydrochloride have been reported. In general, these cases were characterized by excessive consumption of the drug for its central stimulant effect, and have resulted in a psychotic illness manifested by restlessness, mood or behavior changes, hallucinations or delusions. Do not exceed recommended dosage.
Adverse Reactions: Dryness or unpleasant taste in the mouth, urticaria, overstimulation, insomnia, urinary frequency or nocturia, dizziness, nausea, or headache.
Dosage: One 25 mg. tablet b.i.d. or t.i.d. Or one 75 mg Endurets tablet a day, taken by midmorning.
Availability: Pink, square, scored tablets of 25 mg. for b.i.d. or t.i.d. administration, in bottles of 100 and 1000. Pink, round Endurets® prolonged-action tablets of 75 mg. for once-a-day administration, in bottles of 100 and 1000. (B) R3-46-560-B

Preludin® Endurets®
phenmetrazine hydrochloride prolonged-action tablets

They run a good chance of losing weight.

Exercise and Preludin run together in helping patients to lose weight.

Preludin often puts a natural curb on appetite and frequently promotes a sense of well-being. By boosting a dieter's spirit, Preludin may help patients get the exercise you may prescribe.

One Endurets tablet taken between breakfast and midmorning usually provides daylong and early-evening suppression of appetite.

Mild ulcerative colitis may be triggered here...

In mild ulcerative colitis, a number of factors can precipitate an attack: for instance, dietary indiscretion, such as eating raw foods, or emotional overreaction, such as that aroused by financial difficulties. No matter what causes the patient's sensitive colon to "act up," he soon suffers from acute discomfort...and often, from anxiety and apprehension as well. Such patients frequently respond well to adjunctive dual-action Librax® therapy.

Librax combines, in a single convenient capsule, the well-known antianxiety effect of Librium® (chlordiazepoxide HCl) and the dependable anticholinergic/antispasmodic effect of Quarzan® (clidinium Br). Therefore, as Librax helps to relieve the patient's excessive anxiety and reduce his overreaction to stress, it also, at the same time, helps to control hypersecretion and hypermotility, thus relieving spasm and abdominal discomfort.

With Librax, the dosage schedule is simple: 1 or 2 capsules, t.i.d. or q.i.d., will in most cases bring the patient significant relief of both the emotional and physical elements that contribute to his psychovisceral disorder.

Before prescribing, please consult complete product information, a summary of which follows.

INDICATIONS: Indicated as adjunctive therapy to control emotional and somatic factors in gastrointestinal disorders.

CONTRAINDICATIONS: Patients with glaucoma; prostatic hypertrophy and benign bladder neck obstruction; known hypersensitivity to chlordiazepoxide HCl and/or clidinium bromide.

WARNINGS: Caution patients about possible combined effects with alcohol and other CN depressants. As with all CNS-acting drugs, ca tion patients against hazardous occupations r quiring complete mental alertness (*e.g.*, operati machinery, driving). Though physical and ps chological dependence have rarely been report on recommended doses, use caution in a ministering Librium (chlordiazepoxide hydr chloride) to known addiction-prone individua or those who might increase dosage; withdraw symptoms (including convulsions), followi discontinuation of the drug and similar to tho seen with barbiturates, have been reported. U of any drug in pregnancy, lactation, or in wom of childbearing age requires that its potenti benefits be weighed against its possible hazar As with all anticholinergic drugs, an inhibiti effect on lactation may occur.

PRECAUTIONS: In elderly and debilitate limit dosage to smallest effective amount to pr clude development of ataxia, oversedation confusion (not more than two capsules per d initially; increase gradually as needed and tole

or here.

ated). Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

ADVERSE REACTIONS: No side effects or manifestations not seen with either compound alone have been reported with Librax. When chlordiazepoxide hydrochloride is used alone, drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally with chlordiazepoxide hydrochloride, making periodic blood counts and liver-function tests advisable during protracted therapy. Adverse effects reported with Librax are typical of anticholinergic agents, *i.e.*, dryness of mouth, blurring of vision, urinary hesitancy and constipation. Constipation has occurred most often when Librax therapy is combined with other spasmolytics and/or low residue diet.

two good reasons for prescribing LIBRAX®

Each capsule contains 5 mg chlordiazepoxide HCl and 2.5 mg clidinium Br.

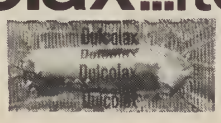
Nutley, New Jersey 07110

Public Enema No. 1

Claim the rewards of sparing your patients the tubes and tribulations of unpleasant enemas.



Compared to enemas, Dulcolax suppositories are a gentler and simpler way to empty the bowel. Gone are the tubing, the "accidents", and the bruised egos. Just one suppository, inserted against the bowel wall, usually brings about an evacuation within 15 minutes to an hour.

In the hospital, order Dulcolax for constipation or bowel cleansing. Your patients will often prefer it to embarrassing enemas. And you can be sure nurses will appreciate the saving in time and effort.

Dulcolax tablets taken at night usually result in a bowel movement the following morning. A combination of tablets at night and a suppository the next morning generally cleans the bowel thoroughly in preparation for surgery or special procedures. Keep in mind, however, that the drug is contraindicated in the acute surgical abdomen.

Dulcolax®...it's predictable

ROBERT E. FARBER, MD, MPH, COMMISSIONER

Baltimore City
health department

BALTIMORE'S HEALTH IN 1968

In a review of health conditions during 1968 in Baltimore city prepared by Matthew Tayback, ScD, Deputy Commissioner of Health, the most important developments noted were:

1. **Remarkable control of those diseases for which vaccines exist to prevent illness**
2. **Extensive illness from acute respiratory conditions for which preventive procedures are limited**
3. **Measurable progress in the fight against tuberculosis**
4. **A determined effort by the City Administration to improve the sanitary level of the residential areas of the City**

Two extensive outbreaks of acute respiratory illness, one in late January, and the other in December due to Hong Kong type influenza, probably caused 1,000,000 days of disabling illness among residents of Baltimore city. Diseases similar in means of transmission (diphtheria-0, whooping cough-23, poliomyelitis-0, and measles-66) in total caused less than 1,000 days of illness. This striking difference is due to the availability of preventive vaccines and to the protective inoculation service and health intelligence systems evolved and maintained by the City Health Department. One may confidently expect that within the near future, vaccines of high potency against the many viruses which cause acute respiratory disease will help reduce the enormous extent of illness caused by these conditions as well as the cost in lost time and in medical care.

In order to understand the nature of health problems in the City one requires detailed knowledge of the characteristics of the population. The latest revised estimates have been made and conform within 1% to the independent calculations of the U.S. Bureau of the Census. Revised population estimates for Baltimore city for the past two years are:

Year	Total	White	Nonwhite
1968 (July)	918,000	505,000	413,000
1967	930,000	523,000	407,000

There is continuing evidence of considerable migration within and in and out of the City. These movements are important not only because they are resulting in marked changes in the social and economic characteristics of the City's population, but also because increasing numbers of our residents are moving to neighborhoods where added social and health services should be provided. In this regard the City Health Department is readjusting its clinics and services to meet the changing needs inherent in the population trends.

Tuberculosis

Tuberculosis is one of the more difficult public health problems which has engaged the attention

of many skilled professionals in Baltimore city. During 1968, the number of newly reported active cases was 640, a reduction of 6.7% from the level of 683 reported in 1967. Although the incidence of tuberculosis in the City is relatively high (70 new cases per 100,000 population) studies of the spread of infection indicate that transmission of tuberculosis is rarely seen among middle-income and upper-income families and that even among the children from economically deprived circumstances, spread of infection is at a remarkably low level. The high level of cases among adults largely is the result of a breakdown in the health of adults infected many years ago with tuberculosis rather than the result of a recent tuberculosis infection. Aside from the economic improvement of low-income families, the Department's continuing control of active infectious cases and the newly established preventive procedures of identifying and treating dormant tuberculosis will be the chief elements protecting the population from this disease.

Maternal and Child Health

Although widely removed from tuberculosis as a health problem, the health of mothers and children is determined by the same factors, namely, social stability, economic support, and availability of adequate medical services. Steady decline in the infant mortality rate over the past six years, from 32.5 infant deaths per 1,000 live births for the two-year period 1961-1962 to 27.6 for the biennium 1967-1968, a 15% reduction, is an indication of the progress being made in this problem area. Substantial further progress could be made in the reduction of infant mortality, if child-spacing patterns could be improved.

Baltimore continues to have a difficult problem in the occurrence of approximately 1,000 live births among unmarried girls under 17 years of age. The City Health Department with the financial assistance of the Thomas Wilson Sanitarium Fund has launched two experimental programs to contend with this problem. One, in cooperation with the Maryland League of Women's Clubs is concerned with improving the social environment of young adolescent girls and provides health education and counseling to encourage sound family-life patterns. The second, in cooperation with Sinai Hospital, provides medical services to assist adolescent girls with family planning when these youngsters, with the consent of their parents, seek such help. These efforts are unique and need considerable further reinforcement and financial support if the City is determined to solve a problem which leads to a myriad of subsequent social, economic and medical difficulties.

An examination of the birth statistics for 1968 shows a substantial further decline in the number of live births among City residents. The total of 16,825 resident births in 1968 is the lowest such figures since 1941. It is 6% below that for 1967 and 28% below the total of 23,262 registered in 1960. These are truly phenomenal changes and by and large will result in considerable reduction in the volume of service required of facilities which deal with young children. The sharp drop in live births has come about as a result of a tendency to smaller families, particularly among low-income groups to whom non-availability of birth control methods prior to 1963 resulted in families larger than those desired. The City Health Department family planning clinics and those operated by Planned Parenthood, as well as the special efforts of the departments of obstetrics of several of the major hospitals, have been the prime factor in achieving this striking and highly desirable change.

As a result of declining fertility, but also as a result of substantial movement of young families out of the City, there is a situation in the white segment of the population which has not occurred previously in the recent recorded history of our community. The number of deaths exceed the number of births. This is indicative of a population segment in which the older age groups are predominant. As a result we are faced with rapidly burgeoning requests for medical and social services to elderly residents whose numbers increase rapidly while, in the white community, the number of children and young adults decline appreciably. During 1968, for example, there were 7,338 deaths among white residents while the number of births was 7,235. By contrast, a more conventional situation was noted in the nonwhite segment of the City's population in which there were 9,590 births and 4,308 deaths contributing to a population increase of 1.3% in this segment.

Among preschool-age children, the chief problems which engaged the attention of health services were those which were seen particularly among families in deprived economic conditions, namely, impaired physical development due to poor nutrition, below-average intellectual development due to inadequate environmental stimula-

tion, and the inaccessibility of satisfactory medical services. In the latter regard, it was apparent that the resources available for medical care of families with limited economic circumstances were being strained to the breaking point, and that two issues would need immediate solution if further difficulties were to be avoided, *ie,* (1) sufficient financing of medical care for all families with low income, and (2) organization of systems of care which use funds efficiently to reach families with medical services which are accessible and understandable. The City Health Department is now engaged in the development of plans to be submitted to the Mayor which, it is hoped, will accelerate a solution of this issue.

Environmental Health

While the City draws its strength from its distinctive position as an industrial and commercial center and as a focus for cultural and university life, it is under increasing pressure to prevent deterioration of its environment. The City Health Department increased its efforts to improve the quality of the air by banning open-air burning. In addition, with a grant from the Federal Government, it launched a vast program of rat eradication, while also assuming a new responsibility for a corps of Sanitary Enforcement Officers.

The end effect of all health services is the preservation of life and the provision of comfort and security of person. For several years, it has been most disturbing to note the steady loss in life due to homicide. In 1968, a further 32% increase in the number of homicides was recorded. Within the past nine years the homicide trend is as shown below.

Year	Deaths	Year	Deaths	Year	Deaths
1960	106	1963	140	1966	185
1961	90	1964	125	1967	205
1962	105	1965	137	1968	267

This increase cannot be attributed to a change in record-keeping practices as the totals for each year are based on certifications made by the medical examiner using standard procedures. A joint attack on this problem by legal, police, and health authorities would appear necessary to stem further increase in the loss of life due to homicide.

Concluding Note

In reviewing our major health problems one gains a sense of optimism when the extent of progress and accomplishment during the past six years is assessed. Among some of the major achievements are:

1. Near eradication of two diseases—poliomyelitis and measles.
2. Vast expansion of services for mothers and infant children resulting in the availability and acceptance of family-planning methods by thousands of mothers from the inner city and in a significant reduction of infant mortality among their babies.
3. Creation of comprehensive health centers for 20,000 children and youth.
4. Increased efforts for the control of atmospheric pollution.
5. Successful establishment of psychiatric services for adults including the creation of an Alcoholism Center.
6. Initiation of experimental programs to solve the difficult and fundamental problem of teen-age pregnancy.
7. A four-fold increase in rodent control work leading to prospects of rodent eradication.
8. Creation of a social-medical service for the care of disabled aged persons residing in their own homes.

These are massive efforts resulting from aggressive leadership and represent significant health gains. The next challenge will be to continue the efforts to organize Baltimore's many health services so that the individual and the family unit can receive the optimum benefits of medical skill and knowledge in a manner which will provide a source of comfort and personal motivation to better health.

** In 1967 included aseptic meningitis.

JERRY SALAN, MD, EDITOR

A Service of the Heart Association of Maryland

the heart page

Recognizing the Acute Coronary Process

If we are to prevent needless death and minimize disability resulting from heart attacks, we must stop trying to diagnose the wrong condition. The emphasis must shift from the detection of myocardial infarction to the suspicion of an "acute coronary process." The danger to life in acute coronary disease arises not so much from myocardial necrosis as it does from acute myocardial ischemia. Most deaths in heart attacks stem from the acute effects of myocardial ischemia (arrhythmia, shock, and failure), rather than from the more chronic results of myocardial necrosis (heart failure, myocardial rupture, and embolism). The patient who recovers from a heart attack with myocardial infarction, an abnormal electrocardiogram, and no angina will live longer and more comfortably than the one who recovers without evidence of myocardial infarction and with a normal resting electrocardiogram, but with angina. Pathologically, this latter group is comprised of "the hearts too good to die." Autopsy often shows not only no recent myocardial necrosis, but frequently not even a recent coronary thrombosis is recognizable.

SIDNEY SCHERLIS, MD

Assistant Professor of Medicine
University of Maryland School of Medicine

Approximately one-quarter of sudden deaths, attributable to coronary artery disease, occurs in persons who have had recent symptoms which were either not recognized or not suspected of being cardiac in origin. Similarly, it has been shown that about 20-25% of patients recognized in periodic examinations to have myocardial infarction, either had no cardiac symptoms, or were not recognized as having coronary disease when they did consult their physicians. These so-called "silent coronaries" too often, I believe, are not so much silent as they are unrecognized. The emphasis, therefore, must be placed not on confirmation of the myocardial damage resulting from interference with coronary blood flow, but on the suspicion that the coronary circulation is being compromised before complications occur.

One need not be a diagnostician to suspect that a patient with severe constrictive chest pain, shock, or heart failure, may have coronary artery disease. Nor is particular astuteness required to conclude that a patient with a grossly abnormal electrocardiogram may have myocardial infarction, especially if serum enzyme tests (SGOT, SLDH, SCPK) are abnormal. This, however, is "closing the barn door after the horse has escaped." Vascular surgeons would not view a colleague with approbation who prides himself upon making a diagnosis of peripheral arterial embolism by waiting for necrosis of the distal portion of the limb

to occur. Neurologists no longer wait for a stroke to appear before attempting to diagnose it or treat the patient who has symptoms suggestive of cerebral vascular insufficiency.

Before discussing the problems and principles involved in the early detection of an acute coronary process, one might ask whether there is any evidence of the fact that such early recognition does benefit the patient. In other words, is there treatment which will either prevent sudden death, or minimize the extent of the possibly ensuing myocardial infarction? I believe that the widespread experience in coronary care units demonstrates beyond question the efficacy of early careful observation and treatment in decreasing the incidence of early death in patients with acute coronary disease. Although it is less readily proved that early treatment helps prevent myocardial necrosis, it does seem quite likely that a heart muscle whose coronary circulation is obstructed will probably suffer less necrosis if fewer demands are placed upon it until its anastomotic circulation has had an opportunity to develop.

In order to facilitate detection and promote treatment, it is necessary to know how often premonitory symptoms occur. The frequency varies in reported series from 30% to 80%. In my own experience, the patient with acute myocardial infarction, who previously has not had symptoms suggestive of coronary disease for days, weeks, or even months, does exist. He is such a rarity that I doubt either my skill in asking the proper questions, or the patient's ability to recall earlier events to prompt diagnosis. When one is dealing with early clinical manifestations of coronary artery disease, there is no substitute for a painstaking history. Often, in the busy emergency room, the patient is questioned about acute complaints and is subsequently admitted to the hospital for treatment. As a result, the opportunity to learn about the early clinical manifestations of the disease is ignored.

In this discussion, the term "acute coronary process" is used rather than "acute coronary thrombosis", or "acute coronary occlusion", because we are not all in agreement regarding the early pathological and physiological changes which convert long-standing, slowly-progressive atherosclerosis to an acute, rapidly-progressive process, which, all too frequently, results in myocardial infarction or death or both.

Clinically, the acute coronary process is frequently identifiable not only retrospectively, but prospectively. In its recognition lies greater promise in the immediate future for preventing death and disability due to heart disease, than the more widespread application of electrocardiography and other laboratory procedures. In fact, many lives might well be saved if the physician, who suspects an acute coronary process, were to rely on his suspicions as the basis for treatment, rather than on an electrocardiogram that might be normal, or not characteristically abnormal at that time.

The symptoms of the acute coronary process are the result of interference with the coronary arterial circulation. The most common complaint is pain. Some patients deny pain but admit to "discomfort", "a strange feeling", or "indigestion". The sensation usually differs from anything that the patient has experienced before, and may be distressing or alarming. It is usually located in the anterior chest, in the central retrosternal area, or across the upper chest. Localized parasternal or costochondral discomfort is usually not cardiac in origin. The discomfort of the acute coronary process which is pressing, constricting, or burning in quality, gradually increases, and then decreases in intensity. Ordinarily, sharp, stabbing pains are not due to an acute coronary process. The coronary pain is not maximum at onset, nor is it related to respiration. It may radiate to the neck, jaw, teeth, ears, arms, abdomen, or back. At times, the secondary areas are more severely affected, and there may be little or no chest pain. The discomfort may be intermittent and inconsistent. It may last for minutes or hours, and usually varies in severity if it is of long duration. Possibly, it may be related to physical activity, emotional stress, exposure to cold, straining at stool, or may occur after a large meal. The patient may feel perfectly well between the episodes, while engaging in normal activities.

Instead of pain, the patient suffering from an acute coronary process may have a pain equivalent—dyspnea, light-headedness, weakness, or a sense of heaviness in the arms. The sudden occurrence of an arrhythmia, heart failure, or anginal pain in a patient who has no previous history of coronary disease, should suggest the possibility of an acute coronary process. Syncope, sudden profuse sweating, or shock may have similar significance.

However, not all patients with chest discomfort have coronary heart disease. Pulmonary embolism, pericarditis, pleurisy, esophageal-hiatal hernia, gallbladder disease, peptic ulcer, cervical

arthritis, and costochondral arthritis may all produce symptoms similar to those of coronary disease. The fact is, nevertheless, that patients with the symptoms described should be suspected of having an acute coronary process and should be treated accordingly, until proved otherwise. At the appropriate time, tests to substantiate this or other diagnoses may be undertaken.

The physical examination may not be helpful diagnostically at this time. The patient may appear well, especially if the discomfort has gone. The heart sounds may be strong, the blood pressure normal, and the lungs clear. If the heart sounds are of poor quality, the heart rhythm abnormal, or the lungs congested, then, of course, heart disease is more likely to be present. If the physical examination reveals no abnormal cardiac findings, the patient still must be treated on the basis of the suspicion of an acute coronary process.

The electrocardiogram may not be abnormal, because the interference with the coronary circulation may not be extensive enough, nor of sufficient duration, to produce myocardial necrosis or ischemia that will affect the electrocardiogram appreciably. On the other hand, diagnostic changes may be present in the electrocardiogram early, or, frequently, they may not appear for hours or days. A changing electrocardiographic pattern is indicative of an acute process, whether or not the abnormalities are typical or extensive. If electrocardiographic abnormalities do not appear, it is possible that the suspicion of an acute coronray process was wrong, or that the treatment was effective in preventing detectable myocardial damage. Such patients may later have clinically recognizable angina pectoris, or exercise tests three to six months later (not earlier) may reveal abnormal electrocardiographic responses.

In the absence of these electrocardiographic abnormalities, serum-enzyme studies, intended to support the suspicion of myocardial necrosis (SGOT, SLDH, SCPK), are rarely of help. They are useful in dealing with a patient whose electrocardiogram is an unchanging one for other reasons, such as, a patient with left-bundle branch block.

This paper, then, is a plea to shift the emphasis from *recognition* of the *ravages* of coronary artery disease, as manifested by myocardial infarction, to *suspicion* and *detection* of the *earlier incipient stages* of the acute coronary process, when the fruits of discovery are so much greater.

SKIN PROBLEMS

Caused by itching due to:

For Safe, Sure, Speedy Relief —
— Get RESINOL GREASELESS!

Medical Scientists have conquered 6 dread diseases in the past decade, but they are largely in the dark, they admit, in finding relief for one age-old ailment—itching

New remedies containing antibiotics have been tested, but have often caused side effects which are worse than itching skin. After many years of research and testing, Resinol Greaseless Cream was developed. . . . A doctor's formula containing safe yet powerful ingredients, Resinol Greaseless contains an amazing, proven "anti-itch" medication called Resorcin, which quickly and effectively relieves most any kind of itching. Try Resinol Greaseless . . . You'll be delighted to find that it really works! At all drug stores. Buy a tube today.

Community Blood Resource Program

The need for a broad based, controlled, and easily researched inventory of the total community blood resource has been evident with blood bankers almost since the advent of blood transfusion therapy. Past and current methods of blood procurement are inefficient, have not changed appreciably in decades, and have not kept pace with the giant steps in immunohematology and transfusion therapy. Technical methodology of transfusion therapy has advanced while administrative methodology to complement these vastly improved technics have lagged far behind and beg to be updated.

Described below is a concept for a program of inventory and control of the total community blood resource. The purpose of this report is to disseminate and test the idea, and to stimulate interest and cooperation, both of which are mandatory for the successful institution of such a program.

The purpose of the program is to provide a comprehensive, current and readily accessible cumulative file of all blood resources in the community, including walking donors, frozen blood, fresh and frozen blood components, rare blood types and whole blood stocks. Such a program would provide a significant contribution to the efficient meeting of community health needs in the area of blood transfusion therapy. By sharing resources, by standardizing procurement methods and by decreasing outdating of blood, such a program would enable the community to supply better the blood needs of its patients.

A program of this sort presents a large administrative problem involving storage and manipulation of large amounts of specific data. However, since this problem is similar to administrative problems common to all blood banks, shared methods are feasible and economy can be expected. A properly organized, computer-supported system can provide this total community blood resource inventory and control. Data storage for the predictable future is not so massive and manipulation is not so complex that a large computer dedicated solely to this project is necesary. The program can be handled by a medium-size, fast, third generation computer on a time shared basis while the same computer is serving other needs and purposes.

A flow chart which condenses and illustrates the salient features of the program is shown in Figure 1. Numerals in the chart refer to subsequent explanatory paragraphs.

(see next page for Figure 1)

(1) The program can accommodate any number of hospitals. The connecting link between the central computer facility and each participating hospital is a teleprocessing terminal. One terminal with keyboard entry and a character printer providing hard copy for audit trail is strategically placed in each hospital. All data

concerning current blood stocks, donors, assurance programs, and patient blood needs are processed rapidly and easily using this terminal. The American Red Cross is an integral part of the program since its resources represent a major portion of the community's total blood resource. The inventory of the Red Cross is entered and continuously updated using this same terminal. Virtually all administrative records of each blood bank are kept in the central facility, including all donor and recipient debit and credit records and the status of all blood, including its condition, characteristics, source, and shelf life. Records that are appropriate only for the use of the individual blood bank can be sequestered to assure use only by that blood bank.

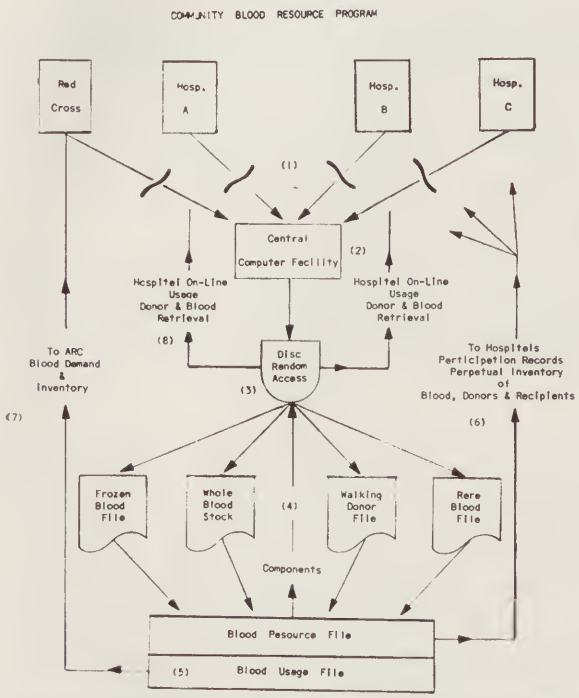

Figure 1—Community Blood Resource Program-Flow Chart

(2) The central computer facility is a portion of a third generation computer. The blood resource program has its own manager, the equivalent of a systems engineer, with supervisory responsibilities for maintenance of the program. The central processing unit of the computer and other peripheral equipment are shared. The additional unshared hardware required at the central facility is one or more disc drive units, depending upon the number of participants.

(3) In such a program random or direct access capability is required for on-line continuous data entry, correlation, and retrieval from all files. Twenty-four hour operation is mandatory and can be arranged with an acceptable increase in overhead expense.

(4) The files shown are examples of data base organization and are not intended to be all inclusive or exclusive of other files. Utilizing appropriate computer programs, the entire data base representing the community blood resource is entered into these files, properly organized and assimilated for utilization as information retrieval. For example, in a type-specific blood assurance program consisting of a preprocessed walking donor file, the recording of preprocessed donors, including blood group and type, serology, antibodies, address, telephone number, and hours of availability constitutes the data base for this file. Retrieval according to specific patient need comes through access to this file and other files (see paragraph 8).

(5) Major correlative files are compiled from individual blood procurement and usage records, and provide records of donor and recipient transactions and hospital participation for individual hospitals. This file also represents the total current community blood resource at any time. Since all donors are listed in the file, together with any characteristics, such as, a history or physical condition that would preclude donation, donors can be cleared for acceptability through the computer prior to phlebotomy. The computer can also help to search for hepatitis carriers by flagging all donors involved in a hepatitis case. A donor involved in two or three cases of post-transfusion hepatitis then can be listed in the computer as unacceptable as a continuing donor.

(6) Monthly usage reports are provided to individual hospital participants. All hospital assurance program records, together with the records of the current status of donors and recipients and individual blood bank statistics, are kept in these files. Automatic notification of donors and recipients by letter is readily available and serves several purposes. For example, yearly queries to donors for change in status or location are advisable for file up-

dating. Similarly, automatic notification of a donation requirement and automatic acknowledgement of a donation are useful. Equally effective are automatic queries to patients and their families requesting replacement for outstanding blood indebtedness.

(7) Daily reports to the Red Cross show the current status of the total community blood resource as well as a prediction of the blood need for the immediate future. Based on today's total blood resource, a prediction as to tomorrow's blood need is made and reported to the Red Cross which gears its phlebotomy activities accordingly. Further, through comprehensive inventory and usage prediction, blood of specific type that is known to be overstocked is immediately processed into frozen blood stock, eliminating the risk of outdating.

(8) With the total community blood resource compiled, organized and retrievable from a central file, the program provides the best source of any specific requirement at any time of the day or night upon request. An inquiry into the system by a participant hospital stimulates a computer search of all files to provide the most suitable blood product from the best location within the community at the time of the request. The computer evaluates whether a specific blood request can be provided from current whole blood stocks, frozen blood stocks or a walking donor file, or whether the specific need cannot be met from within the community. For example, inquiry using the hospital terminal for a specific blood need is made. The computer reports the most readily accessible supply of suitable characteristics or the most suitable and accessible assurance program donor at the time of day the request is made, considering not only the hours of availability of the donor but his geographic location with respect to the requesting hospital. All of this information is available rapidly in response to the individual hospital inquiry; the inquiry and response are provided through the same terminal that is used for data input.

The cost of such a program after the development phase and with the participation of a sufficient number of hospitals has not been determined exactly at this time, but estimates show that the cost can be predicted to be within the reach of, and economically feasible for most blood banks. Because the majority of each blood bank's administrative work load is absorbed by the system, the saving in administrative work load should pay at least for the individual blood bank's teleprocessing terminal. Per unit cost of blood procurement today probably ranges between $10 and $50 depending upon conditions. Significant savings can be realized by computer control to reduce the per unit procurement cost to a minimum in each case as illustrated above. Outdating ranges between 4% and 15% in the average hospital in this area. When translated into dollar loss that can be avoided by computer control, such savings can go a long way toward amortizing the cost of participation in the program. For example, if a hospital uses 3,000 units of blood per year and outdates 300 units at $10 per unit procurement cost, the hospital possibly has already spent more in outdated blood than the cost of participation in the program. The patient is the equal beneficiary since the cost of transfusion therapy is reduced proportionally and significantly, and the patient receives a therapeutic agent that is best suited to his needs, more rapidly and at reduced cost.

Problems incident to the establishment of such a program are formidable and certainly will center about the stimulation of interest and participation of the majority of the major blood users in the community. Rules for acceptable levels of participation would be necessary and some uniformity in blood processing and data entry are essential so that all blood listed on the inventory is of approximately equal status. Since quality in blood banking has been standardized through the various inspection and licensure programs, uniform quality is relatively easy to attain, but the definition of quality and the participation level would seem to be an essential feature of the program. The outlook should be optimistic, however, if one can use past experience in this community as a criterion. For example, other cooperative community blood programs which depend largely upon cooperative effort, such as PULSE and the Maryland Blood Exchange, have been successful. In spite of the obvious problems, it would seem that altruism can prevail and success can be the result. The goal of better, more economical blood provided to the patient more rapidly will make the attainment worth the effort.

The Fortunate One.

Her urinary tract infection reveals itself through pain and discomfort.

While the pain and discomfort of a G.U. infection are anything but pleasant, the patient may be luckier than she realizes. That burning sensation (and/or frequency, urgency, dysuria) is a usually reliable sign of a urinary tract infection. And it's her good fortune that her infection won't go undetected...or untreated.

Azo Gantanol® therapy usually provides analgesic action within one-half hour, while control of the infection begins within two hours. Azo, a specific urinary analgesic, soothes inflamed mucosa to give symptomatic relief. At the same time, the antibacterial component, Gantanol (sulfamethoxazole), achieves therapeutic levels in the blood and urine, with diffusion into interstitial fluids. Azo Gantanol—a good choice when urinary tract infection reveals itself through symptomatic distress.

Before prescribing, please consult complete product information, a summary of which appears on opposite page.

Azo Gantanol®

(Each tablet contains 0.5 Gm sulfamethoxazole and 100 mg phenazopyridine HCl.)

Azo for the pain
Gantanol®
(sulfamethoxazole)
for the pathogens

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Urinary tract infections with associated pain or discomfort when due to susceptible organisms; prophylactically in urologic surgery, catheterization and instrumentation.

Contraindicated in sulfonamide-sensitive patients, pregnant females at term, premature infants, newborn infants during the first three months of life, glomerular nephritis, severe hepatitis, uremia and pyelonephritis of pregnancy with gastrointestinal disturbances.

Warnings: Use only after critical appraisal in patients with liver damage, renal damage, urinary obstruction or blood dyscrasias. If toxic or hypersensitivity reactions or blood dyscrasias occur, discontinue therapy. In closely intermittent or prolonged therapy, blood counts and liver and kidney function tests should be performed.

Precautions: Observe usual sulfonamide therapy precautions including maintenance of an adequate fluid intake. Use with caution in patients with histories of allergies and/or asthma. Patients with impaired renal function should be followed closely since renal impairment may cause excessive drug accumulation. Occasional failures may occur due to resistant microorganisms. Not effective in virus and rickettsial infections.

Adverse Reactions: Headache, nausea, vomiting, urticaria, diarrhea, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, skin rash, Stevens-Johnson syndrome, injection of the conjunctiva and sclera, petechiae, purpura, hematuria or crystalluria may occur, in which case the dosage should be decreased or the drug withdrawn.

Dosage: Adults—4 tablets initially, then 2 tablets morning and evening.

How Supplied: Tablets, bottles of 50.

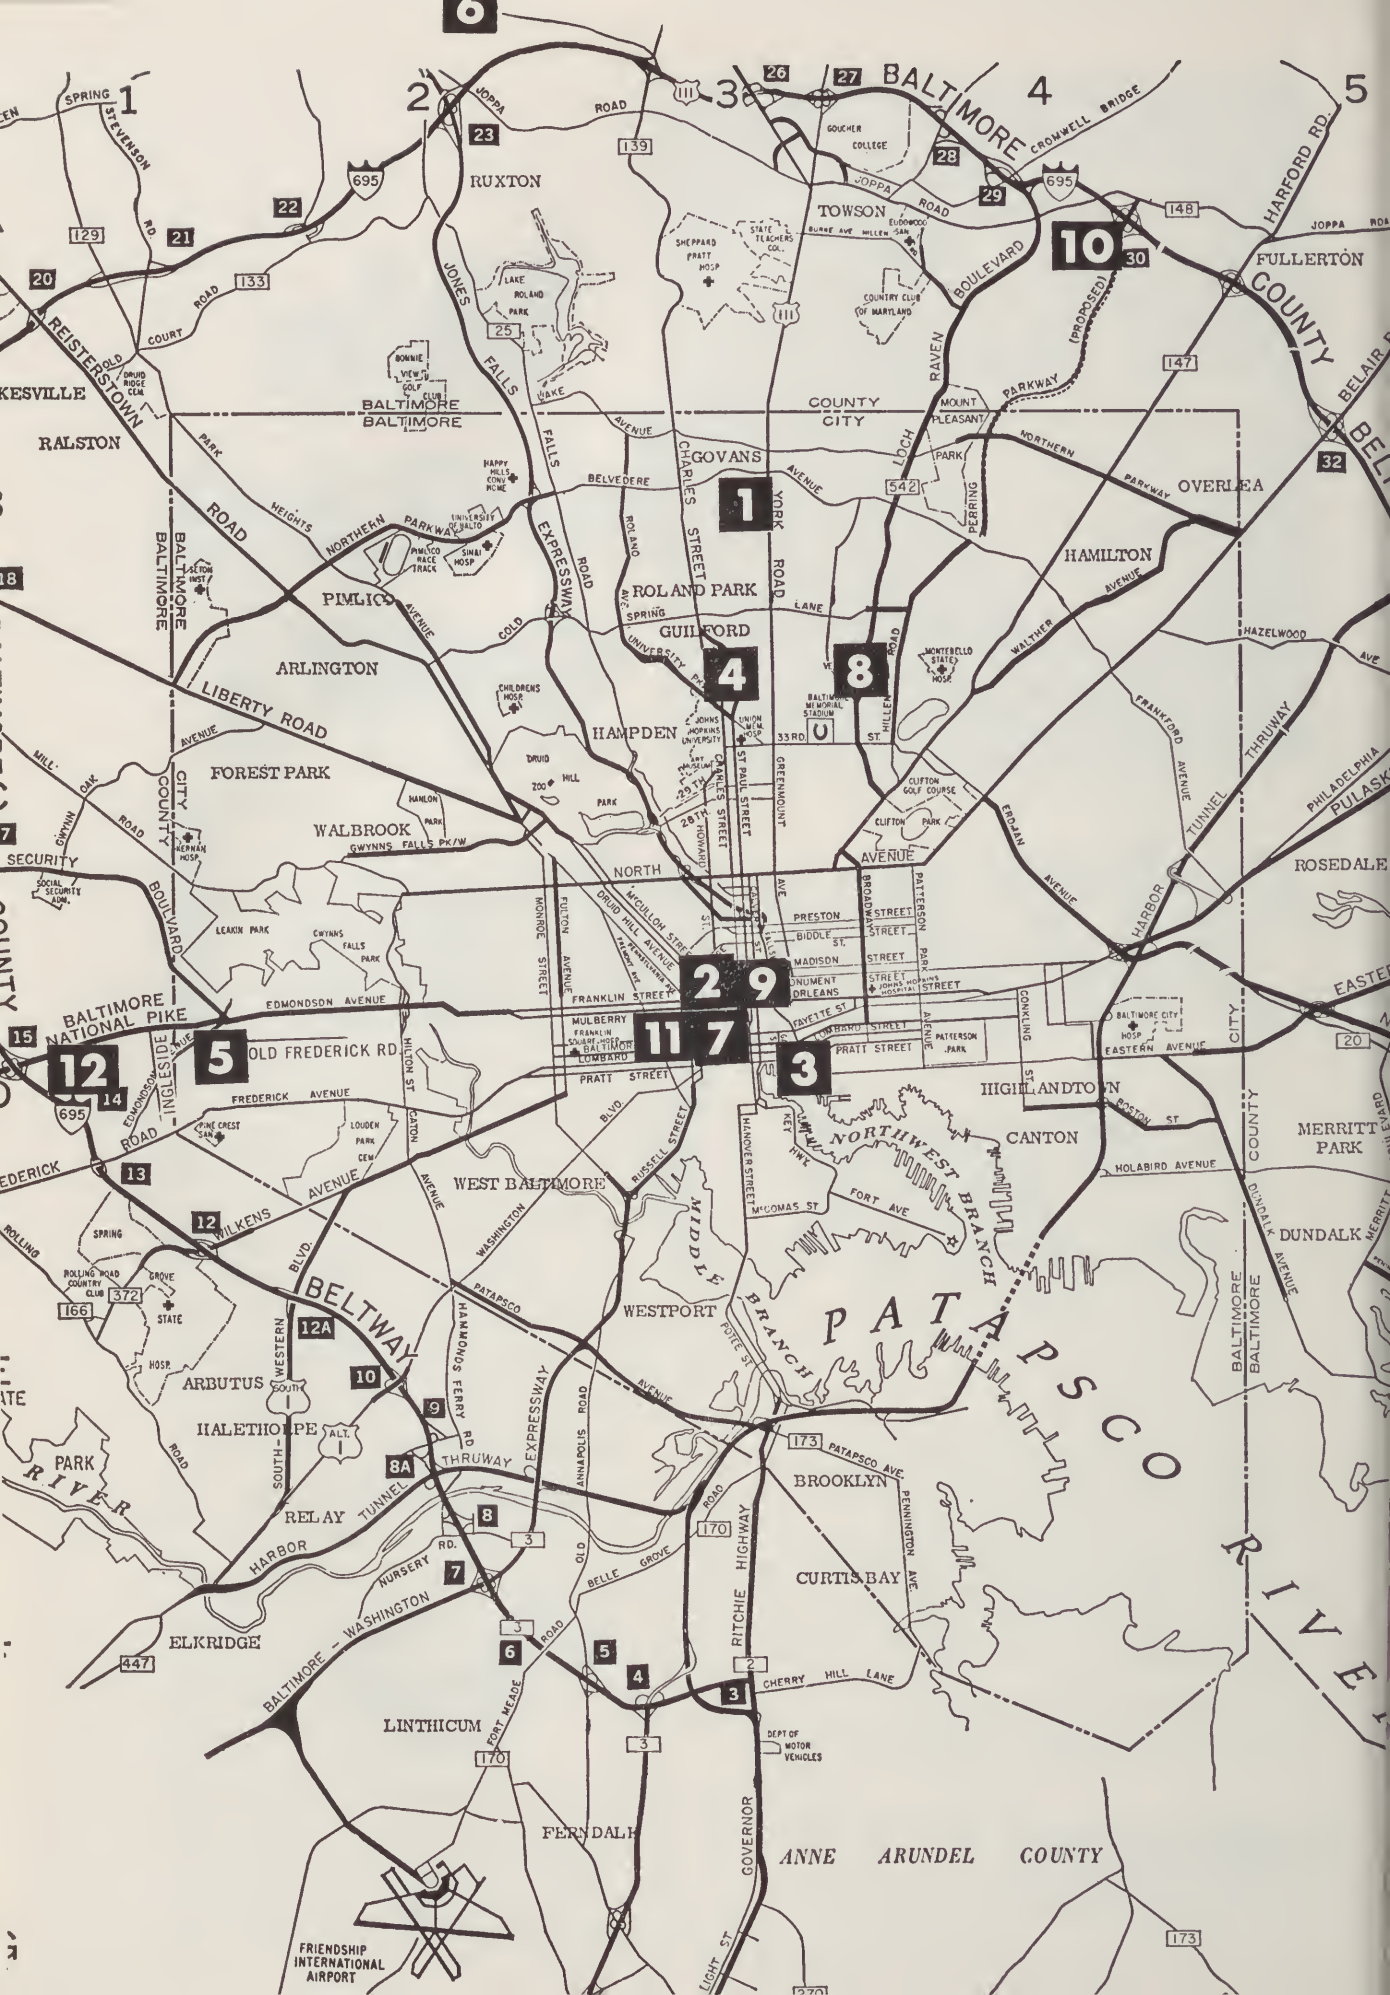
We lease car,

not cars (plural). Car (singular). When a professional man like you wants just one car.



We do one-car-at-a-time leasing with plans particularly appropriate for the professional man. Plans designed to give you the same advantages as enjoyed by big companies that lease.

These advantages include: the new '69 you want as you want it, no capital tied down in a depreciating asset, no separate maintenance or insurance bills, convenient service without extra charge at thousands of "Happy Motoring"® stations throughout the United States, exact transportation costs records on a single monthly bill for tax accounting, no trade-in problems or losses.

Many physicians and surgeons are now leasing. With good reason. Ask your nurse or secretary to drop us a note, or call us, for a detailed booklet explaining the Humble Leasing Plan.

Colorado Reports 120 Abortions

During the first eight months of Colorado's new abortion law, 120 legal abortions have been performed according to a report from the Colorado State Health Department.

Nine of these abortions were performed on rape victims, two were suicide risks, 50 underwent the operation for psychiatric reasons, 22 were granted abortions because their pregnancies presented a physical danger to the mother or child, and 37 cases were for other reasons.

According to the report, 29 of the women on whom abortions were performed resided outside the state of Colorado.

Before the law was liberalized less than 40 therapeutic abortions were reported annually in Colorado.

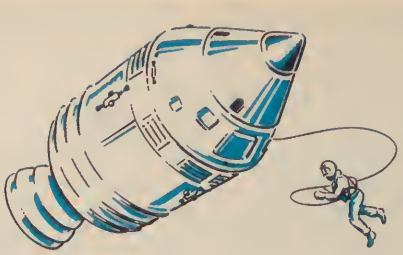
heavenly relief
for unearthly cough

Benylin®
EXPECTORANT

Each fluidounce contains: 80 mg. Benadryl® (diphenhydramine hydrochloride, Parke-Davis); 12 grains ammonium chloride; 5 grains sodium citrate; 2 grains chloroform; 1/10 grain menthol; and 5% alcohol.

An antitussive and expectorant for control of coughs due to colds or of allergic origin, BENYLIN EXPECTORANT is the leading cough preparation of its kind. BENYLIN EXPECTORANT tends to inhibit cough reflex... soothes irritated throat membranes. And its not-too-sweet, pleasant raspberry flavor makes BENYLIN EXPECTORANT easy to take.

PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this preparation. Hypnotics, sedatives, or tranquilizers if used with BENYLIN EXPECTORANT should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENYLIN EXPECTORANT.



ADVERSE REACTIONS: Side reactions may affect the nervous, gastrointestinal, and cardiovascular systems. Drowsiness, dizziness, dryness of the mouth, nausea, nervousness, palpitation, and blurring of vision have been reported. Allergic reactions may occur.

PACKAGING: Bottles of 4 oz., 16 oz., and 1 gal.

Parke, Davis & Company

PARKE-DAVIS

410R69

Man in space, now fait accompli, re-emphasizes the importance of Uro-Phosphate therapy. Research into the effect of space travel on the astronaut reveals that weightlessness causes loss of bone calcium. As the bones are required to bear less and less of the weight of the body they lose calcium, increasing the calcium content of the urine. When physical activity is reduced, the acidity of the urine should be adjusted to keep increased calcium in solution . . . . a prophylaxis to prevent kidney or bladder calculi.

Uro-Phosphate®

NOW A SUGAR-COATED TABLET

Each tablet contains: METHENAMINE, 300 mg.; SODIUM ACID PHOSPHATE, 500 mg.

Uro-Phosphate gives comfort and protection when inactivity causes discomfort in the urinary function. It keeps calcium in solution, preventing calculi; it maintains clear, acid, sterile urine; it encourages complete voiding and lessens frequency when residual urine is present.

Uro-Phosphate contains sodium acid phosphate, a natural urinary acidifier. This component is fortified with methenamine which is inert until it reaches the acid urinary bladder. In this environment it releases a mild antiseptic keeping the urine sterile.

Uro-Phosphate is safe for continuous use. There are no contra-indications other than acidosis. It can be given in sufficient amount to keep the urine clear, acid and sterile. A heavy sugar coating protects its potency.

Dosage:

For protection of the inactive patient 1 or 2 tablets every 4 to 6 hours is usually sufficient to keep the urine clear, acid and sterile.

2 tablets on retiring will keep residual urine acid and sterile, contributing to comfort and rest.

A clinical supply will be sent to physicians and hospitals on request.

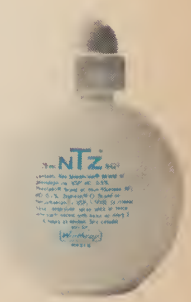
WILLIAM P. POYTHRESS & COMPANY, INC., RICHMOND, VIRGINIA 23217

Manufacturers of Ethical Pharmaceuticals

"The inconvenience of a cold"

or a cold, NTZ® Nasal Spray provides rapid relief of asal symptoms. Relief starts with the first spray which pens the inferior part of the common meatus. A second pray, a few minutes later, will shrink the turbinates to elp provide sinus drainage and ventilation. Dosage ay be repeated every three or four hours as needed, r temporary relief of symptoms. NTZ is well tolerated ut overdosage should be avoided.

s a sinusitis deterrent, NTZ Nasal Spray can be used to eep the nasal passages open during a cold to help pre- nt development of acute sinusitis—or to help prevent e acute condition from becoming chronic.



upplied: NTZ Nasal Spray, plastic squeeze bottles of ml.; NTZ Nasal Solution, bottles of 30 ml. (1 fl. oz.) th dropper.

NTZ is more than a simple vasoconstrictor. It contains

Neo-Synephrine® (brand of phenylephrine) HCl 0.5 per cent, the major component, virtually synonymous with fast, efficient but gentle nasal vasoconstriction.

Thenfadil® (brand of thenyldiamine) HCl 0.1 per cent, topical antihistamine for reduction of rhinorrhea, sneezing or itching. It combats the allergic reactions that may occur in colds or sinusitis.

Zephiran® (brand of benzalkonium, as chloride, refined) 1:5000, antiseptic preservative and wetting agent to promote penetration and spread of the formula.

Winthrop Laboratories, New York, N.Y. 10016 Winthrop

THE BETTMAN ARCHIVE

Just one tablet at bedtime • Prevents painful night leg cramps • Permits restful sleep

How many of your patients stamp their feet at night and lose sleep because of painful leg cramps? Unless prompted, they usually fail to report this distressing condition and suffer needlessly.

One tablet of QUINAMM at bedtime usually controls distressing night cramps and permits restful sleep with the initial dose.

Prescribing information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Side Effects/Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

PHILADELPHIA, PENNSYLVANIA 19144

ANTISECRETORY SEDATIVE

Antrocol

Antrocol provides the prompt, predictable antisecretory action of the belladonna alkaloid, atropine, fortified with sedation and blended with Bensulfoid, contributing to slow, even absorption.

Each Antrocol tablet or capsule contains 0.324 mg. of atropine sulfate, which is twenty-four thousandths of a milligram more than the smallest effective dose specified in U.S.P., Vol. 17. This slight increase in the smallest effective dose of the antisecretory factor (atropine) is all the average patient can tolerate without discomfort.

One Antrocol tablet or capsule taken three times daily lessens emotional stress and maintains a gastric function that is not conducive to the development of peptic ulcer.

Antrocol is also useful in the treatment of peptic ulcer. Dosage up to 8 tablets or capsules per day to obtain the desired antisecretory titer. When ulcer has healed, one Antrocol tablet or capsule morning and evening gives protection against recurrence.

Each tablet or capsule contains:

Atropine Sulfate	0.324 mg.
Phenobarbital (may be habit forming)	16 mg.
Bensulfoid, see white section P.D.R.	65 mg.

Side-effects: Toxic levels of atropine may produce flushing, dry mouth, blurred vision, tachycardia, or urinary retention. Precautions: Do not use in glaucoma. Use cautiously in prostatic hypertrophy.

Federal law prohibits dispensing without prescription.

From the Subcommittee on Alcoholism of the Medical and Chirurgical Faculty of the State of Maryland

Management of Acute Phases of Alcoholism, Including Delirium Tremens

Clinical experiences on 412 patients hospitalized for acute alcoholism during the period of July 1967-July 1968 were presented by representatives from Provident Hospital, Church Home and Hospital, Spring Grove State Hospital, and Baltimore City Hospitals during a conference on October 9, 1968 at Baltimore City Hospitals.

The conference was set up to review the experiences with the hope of generating interest in general hospital treatment of patients suffering from acute alcoholism and in trying to improve the management of such patients. Conference moderator and reporter was E. G. Beacham, MD, Chief, Tuberculosis Division, Baltimore City Hospitals.

Esteban Mezey, MD, Assistant Chief Hospital Physician, Metabolic Unit, Alcoholism Grant Program, Baltimore City Hospitals, reviewed the physiological and biochemical aspects of acute withdrawal from alcohol.

Dr. Mezey stated that the withdrawal symptom complex principally consists of a state of increased nervous excitability manifested by increased motor, perceptual and autonomic activity. Magnesium deficiency may be responsible for some of these symptoms, but it is not the major cause—especially in the case of delirium tremens.

The appearance and intensity of withdrawal symptoms correlate with the amount of alcohol consumed and the length of the period of intoxication. The depressant action of alcohol causes a reduction in central nervous system activity which will register on an electroencephalograph. If cessation of alcohol intake is abrupt, hyperactivity is registered by the appearance of transient spikes and sharp waves of rhythmic paroxysmal discharges.

Due to the inhibition of anti-diuretic hormone production following acute alcoholism, diuresis is often seen. With chronic alcoholism there is a marked water and electrolyte retention. The clinical state in this case may depend on factors caused by the alcoholism and the condition of the liver.

Alcohol, in *in vitro* preparations of brain and other tissues, inhibits the active transport of sodium and potassium across membranes. Such effects could possibly explain the changes in fluid and electrolyte balance and depression of the central nervous system, as well as the hyperexcitability noted in the withdrawal syndrome.

Roland Smoot, MD, Chief of Medicine, Provident Hospital, reported on 124 patients (100 male, 24 female) who were seen on a voluntary basis in the hospital's Detoxification Unit between January and July, 1968.

Most of the patients had imbibed alcohol up to one or two hours before admission. Immediately upon admission, most of the patients were given chlordiazepoxide (Librium), 100 mg intramuscularly, then placed on 25 mg orally, four times daily. Additional intramuscular doses were given as necessary. Intravenous fluids were seldom

used since juices and other oral fluids were available at the bedside. Supplemental vitamins and antacids were given, and chloral hydrate was given at bedtime, but paraldehyde and barbiturates were not included in the treatment. Convulsive disorders were controlled with amobarbital (Amytal) or diphenylhydantoin (Dilantin).

Visitors were limited to family and AA members.

According to Dr. Smoot, the patients generally slept well the first night, improved rapidly, and were discharged in five to six days. The patients developed a minimum of complications, and none of them developed DTs. He felt that acute alcoholism could be treated in a general hospital without disturbing the equilibrium of the institution.

Albert Nahum, MD, Director of Medical Education, Church Home and Hospital, presented his study of 32 admissions (19 male, 13 female) spanning the period of July, 1967 to January, 1968.

Since 1963, Church Home has had a cooperative hospital treatment program with the Alcoholism Clinic of the Baltimore City Health Department. Patients are generally admitted through the clinic program or by private physicians.

Upon admission, the patients were given a complete physical examination and laboratory work up, plus chest and skull X-rays and liver-function tests. A complete history was also taken. Some of the patients received 100 mg of chlordiazepoxide every four hours, and 50 mg of promazine (Sparine) every four hours for 24 hours intramuscularly. On the second to fourth day an overall evaluation was made and long-range plans were established. For other patients, a regimen of disulfiram (Antabuse) was prescribed; chloral hydrate was given at night. Paraldehyde was not used.

The patients stayed an average of five to ten days. There were few complications, possibly because no patients were admitted with delirium tremens or in a comatose condition.

Spring Grove State Hospital's representative reported on 214 patients with acute alcoholism seen January 1 through June 30, 1968. **Ferdinand Massari, MD,** Director of Alcoholism Rehabilitation Unit, stated that during this period there was a total of 2,130 mental hospital admissions of which 806 (38%) were diagnosed as alcoholics. Most of the patients in the latter category were treated in general medical wards. Less than one-third of the patients suffering from acute alcoholism were treated in the alcoholism unit.

Treatment in the unit consisted mostly of paraldehyde, although chlordiazepoxide, thioridazine hydrochloride (Mellaril), hydroxyzine pamoate (Vistaril) and other drugs were used. Depending on the size and condition of the patient, 8-10 ml of paraldehyde every four to six hours was administered. Occasionally, 100 mg of chlordiazepoxide was given every four hours intramuscularly before the patients were switched to paraldehyde. Vitamins were dispensed; milk and orange juice were freely available on the ward. No fluids were given intravenously.

The average age of the patients was 45. Most of them stayed four days on the unit then were sent to a dormitory for chronic care. Only four of the 214 developed seizures while on paraldehyde and two of these patients had a history of seizures. Liver-function studies showed 86 patients had SGOT/PT over 200 levels, all except three returned to normal in two weeks. Three cases of active tuberculosis were found.

Dr. Massari concluded that most of his patients had been drinking for years, yet had maintained family and social ties. He felt that because many of the patients complained of anxiety, which was not relieved by sedation, drugs should be discontinued as soon as possible.

Alcoholism patients are treated in general medical wards at Baltimore City Hospitals. **Bruce Bucher, MD,** Medical Assistant Resident, reported on 42 patients (36 male, 6 female) seen January 1 through July 30, 1968. The average age of the patients was 44. Thirteen of the patients were admitted with delirium tremens, one with DTs and comatose, two suffering from hallucinations and alcoholic coma, and two were diagnosed with tremulousness. Twenty-nine of the 42 admitted to drinking alcohol within 12 hours prior to admission.

Because of the variation in tests and range of results, no general comments could be made about the laboratory findings. Hematocrits averaged 38 mm; WBC averaged 9,300 (4,200-18,500); platelets 17/42 averaged 154,000 (normal range: 200,-000-400,000); two patients had hypoglycemia on admission; many had elevated SGOT/PT.

Treatment was varied although paraldehyde was the only sedative mentioned for 28 patients. Chlordiazepoxide and paraldehyde were given to two patients and chlordiazepoxide, alone, to four patients. Fourteen required intravenous fluids. There were seven deaths (16%)—two related to

pneumonia and septicemia; one to subarachnoid hemorrhage; one to ruptured abdominal aneurysm; and one to tuberculosis. Hospital days averaged 12 (actually eight if five patients are excluded because of long-term treatment for concurrent diseases).

Louis Faillace, MD, Chief of Psychiatry, Baltimore City Hospitals, criticized the lack of definition in the above presentations and stressed the difficulty in comparing widely varying programs.

He cited a study at Boston City Hospitals in 1952 where in 266 consecutive alcoholism admissions, acute inebriation was diagnosed in 21%; alcoholism and tremulousness in 34%; hallucination and tremulousness in 11%; acute alcoholism and hallucination in 2%, and delirium tremens in 5%.

Dr. Faillace suggested that all drug regimens seemed to work for the people using them.

In a brief preliminary report on a psychological study at Baltimore City Hospitals, it was suggested that patients with acute alcoholism, as compared with chronic alcoholics and non-alcoholics with other acute or chronic conditions, had difficulty in recalling information given during the acute alcoholism phase and that this period of poor recall lasted about three weeks. This implies that instructions and discussions held during the acute phase would be of limited value, and that a more appropriate time for such discussion would be after this three-week period.

John Hirschfeld, MD, President of the Baltimore Area Council on Alcoholism, commented on 30 private patients—40% female—who have been treated in general hospitals since 1962. In most cases he administered chlordiazepoxide and promazine and frequently noted underlying medical conditions and a special problem regarding burns of groggy cigarette smokers.

Harry Klinefelter, MD, Assistant Professor of Medicine, The Johns Hopkins University School of Medicine, added that he thought that patients suffering from acute alcoholism could rarely be treated at home. He stated he dislikes paraldehyde because of its odor, possible addictive properties, and because it could depress respiration.

Continuing on the subject of drugs, **Conrad Acton, MD,** related his experience with 11,000 cases of acute alcoholism treated in the Baltimore City Jail over a three-year period (1963-66). Only seven deaths occurred (excluding hospitalized patients). He used thioridazine hydrochloride and fluids orally as basic treatment.

Julius Krevans, MD, Chief of Medicine, Baltimore City Hospitals, stressed the need for superb medical care facilities for the treatment of acute alcoholism. He mentioned the vast differences in patient types and problems in different hospitals; the dangers of all drug regimens, specifically in cases of hypotension if phenothiazine derivatives are used; and the incidence of depressed respiration with most sedatives. He urged careful plans for, and objective evaluation of treatment programs.

Maxwell N. Weisman, MD, Director of Alcoholism Programs for the State Department of Mental Hygiene, seconded this point of view and asked that attempts be made to establish a rationale and criterion for medical regimens.

The conference was successful in emphasizing and confirming the urgent need for uniform, statewide general hospital programs for the treatment of acute alcoholism. Uniformity must be established in the definition of terms, acute treatment plans, evaluation of patients and treatment regimens, and follow-up programs.

It was demonstrated that the establishment of such a program did not and would not hinder the administration of a hospital.

with South High athletes, moments after his son, Mac, was awarded the Principal's Trophy at the 12th Annual All-Sports Banquet. The problem of available backup beds in the county was approached by a resolution to open the 50 unused beds at Western Maryland State Hospital.

In April, John C. Stauffer, MD, took off again, this time to Pakistan with N.A.I.D. for one and one-half years. His family accompanied him. His latest address is J. C. Stauffer, MD, PMRC; 6 Birdwood Road; Lahore, Pakistan (25¢ airmail postage—no enclosures).

Ladies Night in May at the Airport Inn was filled with suspense, awaiting the flight of the Hon. Charles M. Mathias, Jr. Due to a storm, he "flew" in by car. The meeting was the largest ever and the crowd heard "Mac" speak of some of the national problems as seen thru the eyes of the legislator. Sheriff Charles E. Price was given the Layman of the Year award for outstanding community service. Also Ralph S. Stauffer, MD, was presented a 50-year pin, he was speechless.

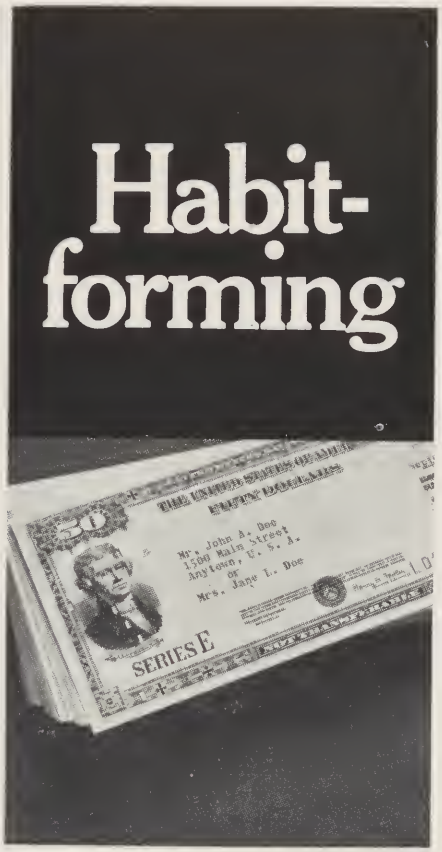
"Weekend with Doctors", sponsored by the Heart Association of Maryland, took three Washington countians to Frostburg State Teachers College in June. Dr. Kehne was keynote speaker with Dr. Gist, speaking on obstetrics and R. A. Young, MD, pediatrics. In Cumberland, Western Maryland Heart Association awarded a medallion and certificate of merit to Dr. Young, the first president of the amalgamated group. John H. Hornbaker, MD, was singled out for his work on the medical advisory committee, and for receiving sanction to establish a cardiac diagnostic center, both in Hagerstown and Cumberland. This county is represented by Howard N. Weeks, MD, Dr. Young, R. T. Binford, MD, and Dr. Hornbaker on the board. Also in June, awards were given to two graduates from the nursing school. The scholarship program has placed the first recipient in medical school and has four high school graduates under stipend.

In September the co-sponsored Lederle Sym-

posium on the "Problems of Sexuality Encountered in Clinical Practice" was an outstanding event featuring Joseph B. Trainer, MD, University of Oregon Medical School; Paul J. Fink, MD, Hahnemann Medical College; and Beverley T. Mead, MD, University School of Medicine, Omaha. This program set forth future expansion of the sex education program in Washington County Schools with the cooperation of the medical society. On September 29, 1968, the new wing of the Washington County Hospital was dedicated. This was the major part of a $5.5 million expansion program and includes the emergency room, operating room, intensive care unit, and EEG lab. It increases beds to 475 and makes the hospital the largest in Maryland outside of Baltimore.

Our theme at the local Health Fair was a pointed exhibit of the seat belt problem, using photographs of local accidents and the AMA exhibit. We have received thanks from accident victims whose lives were saved by seat belts, used only after seeing this exhibit.

Harry D. Bowman, MD, and Ralph F. Young, MD, were granted Emeritus status. J. Walter Layman, MD, has requested same and has been so recommended to the House of Delegates.



Worcester County Medical Society

The Worcester County Medical Society elected new officers recently, naming Francis J. Townsend, MD, of Ocean City to serve as president in 1969.

Other officers are: F. S. Waesche, MD, of Snow Hill, vice-president; and Norman Sartorius, Jr., MD, of Pocomoke, secretary-treasurer.

Delegates are Dr. Townsend and Robert C. Lamar, MD, of Snow Hill. Named to be Censors were Charles Trader, MD, of Pocomoke, 1969; Dr. Lamar, 1970; and Lloyd O. Long, MD, of Snow Hill, 1971.

The society also voted Dr. Long in as an official member.

When you stack one U.S. Savings Bond on top of another, it becomes a habit that's tough to break and hard to beat. That's because it's so painless. Just tell your employer or banker to set aside a regular amount for you before you have a chance to spend it. Sign up today.

New Freedom Shares

Bonus opportunity for people who buy Bonds through the Payroll Savings Plan or Bond-a-Month Plan — a new U.S. Savings Note called Freedom Shares. It pays a higher rate of interest and matures faster. Get all the facts where you work or bank.

U.S. Savings Bonds, new Freedom Shares

BENEFITS OF CONSULTATION

Consultation benefits both the patient and the physician. An additional opinion gives assurance to the patient and his family; it supports your own judgment; it provides positive evidence of good medical practice if you are sued.

Consultation is advisable:

1 — If the patient wishes it.

2 — In difficult cases, especially fractures, where there are two or more acceptable methods of treatment.

3 — Whenever the patient doesn't progress as he should.

4 — If you feel there are aspects of a case that are beyond your experience.

5 — When you feel that the patient is "suit-prone."

The prompt identification and treatment of complications and bad results are all-important in preventing malpractice suits. If a suit does result, it is most helpful to be able to show that another physician was consulted.

Dysfunctions of the Keogh
or
What to do until help arrives

This article is designed to provide guideline information in regard to the subject matter covered. It is not intended to provide, nor should it be construed, as offering legal advice or counsel. For such advice or counsel, we refer you to your attorney. In addition, this article is intended to comply fully with the rules, regulations, and ethics of the National Association of Bankers, Life Underwriters, Security Dealers and, of course, to all local, State and Federal laws and regulations.

The abnormal pathology of Keogh meets with a set of signs and symptoms, which, to the uninitiated, present an ominous picture of morbid possibilities, analogous to the subjective response of the sophomore medical student upon first exposure to morbid pathology.

Be of good cheer: All that looks ominous is not necessarily the reality of danger. In actual fact, dysfunctions of the Keogh occur quite infrequently; the misplaced apprehension stimulated by the unfamiliar is quite out of proportion to the actual danger. But the pathology makes for an interesting literature.

While Keogh was conceived in 1951 (the embryo then being known as the Jenkins-Keogh syndrome), the infant did not emerge from the womb of its mother, the Internal Revenue Code, until 1962. Not atypical of such offspring, the child is verbose, unnecessarily complex, ambiguous, ultrasensitive to the slightest stimulus, and above all, deceptively simple in appearance.

It is regrettable that much of the current Keogh literature unintentionally supports the mistaken concept of Keogh as a simple piece of legislation. Actually, nothing could be further from the truth: A biopsy of the law, together with extensive practice in this field, directly contradicts such a notion. Evidence of dysfunctions of the Keogh has become increasingly available. Examples of the more common types are offered herewith:

I. You didn't contribute as much as you could have . . . (or as much as you were supposed *to contribute by the terms of your plan). You agreed to contribute* 10% *of your income and you only contributed 7% of your income.*

If you didn't have a secretary included in your plan, I wouldn't worry about it. I think the Internal Revenue Service will forgive you. Technically, you may have violated the terms of your plan, but since *you're* the only loser, I repeat: I wouldn't worry about it. You lost your tax-saving deduction on the additional 3%, of course, but you're the only loser, so forget it.

I presume that you want to know whether you can put in *13% next* year—that is, your regular 10% plus the 3% which you first overlooked.

I'm sorry: 10% is your limit in any year.

Now, on the other hand, if you have a secretary included—that's a slightly different story.

Once again, you may have technically violated the requirements of your plan, but at a slightly more serious level. After all, 10% was your commitment to her, and she has the right to expect you to live up to it. Under the terms of many, if not most, Keogh plans, you could put in the additional 3% for her right now—this year. I'd do it, if I were you; and I'd even add some interest—at a reasonable rate—say, 4%, figuring from the end of last year. You can deduct this 3% contribution for her this year (1969), and later on, when you contribute your 10% for *this* year, you'll contribute the 10% for *her,* too. That'll give her *13%* for the year, while you only get the benefit of *10%*. Yes, it does seem possibly a bit unfair, but—the law, you know. . . .

II. Your secretary became eligible during the year and you completely forgot to contribute for her.

That's a most unfortunate oversight. I'm afraid Internal Revenue may disallow your deduction for this year. One has to be careful about these things.

III. You made a contribution of $2,500 but discovered later that you had over-*contributed; you were entitled only to a deductible contribution of $2,100.*

Yes, this sort of thing happens from time to time. Well, what the results of this "excess-contribution" (legal parlance) may be will depend on several factors, and the first of these is whether or not you have an employee who is in Keogh with you.

If you have *not,* Internal Revenue will probably notify you in due time that you have made an "excess-contribution" and will suggest that if you don't remove it forthwith, you will suffer several penalties. Of course, you don't have to wait for the notice. (*I* wouldn't—I'd take action right away), but in any event, you'll have to get back your "excess-contribution", correct your income-tax return and pay Uncle Sam what you owe him.

Now, on the other hand, if you have an employee *in the plan,* with her participation came an additional privilege: that of contributing an *additional* 10% (or $2,500) on a *non-deductible* basis. (You may wonder why on earth you should even consider contributing an additional amount which is *not* tax-deductible. There's an excellent reason: You will pay no income taxes on any of the dividends or capital-gains which this additional contribution makes for you. In other words, the *earnings* are tax-free. And that can be a *mighty important* reason!)

Incidentally, in order to do this, the *particular* Keogh plan which *you* adopted—there are dozens of different Keogh Plans—must *give* you this privilege . . . of making these additional contributions; and—extremely important—should allow you yet another privilege: the right to take this money *out* whenever you wish. The law permits both, but many Keogh plans, unfortunately, are not as liberal as the law.)

If, however—as I said before—you *do* have an employee in the plan with you, and *if* your Keogh plan permits you to make these *additional* non-deductible contributions, and *if* you either, a)—didn't take advantage of this privilege, or b)—didn't contribute as much *additionally* as you were permitted, then: this "excess contribution" can be "poured-over", so to speak, from the *deductible* part to the *non*-deductible part, in which case you will *not* have to take it back, you'll simply have to correct your income-tax return, showing your *deductible* contribution as $2,100 (the limit you said you were permitted to make), also showing a *non*-deductible contribution of $400. (Incidentally, if, as and when you make these *non*-deductible contributions, you *really* should keep a separate record of them . . . just the proper notations on your check stubs will help. It's *most* important from a tax-point-of-view that you know exactly, on the one hand, how much you contributed as a *deductible* item, *and what that money was invested in,* and, on the other hand, how much was contributed on a *non*-deductible basis, and what *that* money was invested in.)

Of course, if you had already made a *non-deductible contribution* of as much as you were permitted to contribute, then we're back to the "excess-contribution" again with which we started this section of this article; you'll have to get back your "excess-contribution", correct your income-tax return and pay Uncle Sam what you owe him.

IV. You made the same contributions this year as you made last year, forgetting completely that there had been salary-changes.

(I think that a re-reading of Sections I and III of this article will throw some light on the probable sequelae.)

V. You made the contribution too late to reach the Trustee or Insurance Company on time.

Yes, we see a "fairish" amount of this. I suggest that if you mail your contributions during the last 5 days of the year, you mail them by either Certified or Registered Mail—and keep the receipt. You should have no further problem with this. But if you have no such proof of timely mailing, I'm afraid you're out of luck—you'll lose your deduction for the year. (There simply *must* be a line drawn *somewhere,* mustn't there—.)

VI. You bought an apartment house (or some other kind of un-*incorporated business), and with it you acquired another employee who was eligible for inclusion in the plan, and you didn't know that the law required this, and so you didn't contribute for him.*

Yes; an unfortunately dangerous trap for the unwary, particularly because it's *so* easy to overlook. I'm afraid you're going to lose your tax-deduction for the year. *Do* try to keep this sort of thing in mind.

VII. You took in a partner or partners; or added a partner, or partners; or changed a partner, or partners.

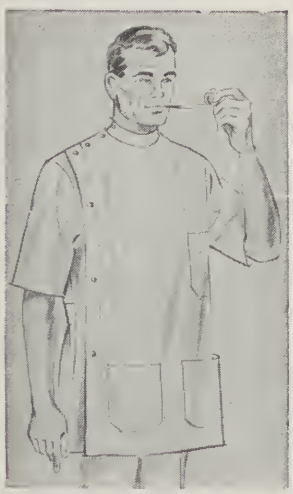
Don't make me go into this—this way lies madness. My best advice: Make the patient comfortable, apply artificial respiration and call for professional assistance immediately.

VIII. You're over 70½ years old, so you didn't go in because you knew (!) that this wasn't allowed after age 70½.

Poppycock! Of *course* you can go in . . . and get your deduction, too! (Government Retirement Bonds might be your best bet at this age.)

IX. You're less than 59½ years old, you bought U.S. Retirement Bonds and now you find out that you're not eligible for tax-savings because you're not really "self-employed". (The things that happen in this world!)

Write the Bureau of the Public Debt, c/o the Fiscal Service of the Treasury Dept., and tell 'em your sad story; you may be able to get your money back.



As you may have noticed, the literature concerning these dysfunctions is, unfortunately, well-nigh non-existent. We submit this contribution in the general interest.

We cannot help but conclude, however, that post-sale attention seems deplorably lacking. We urge that the necesity for *competent* and *continuous* attention not be overlooked.

Exposure to Cold Environment and Rhinovirus Common Cold

Volunteers without antibody to a rhinovirus strain were subjected to a cold environment before and after inoculation with the viral strain. No effect on the illness was demonstrated, despite popular belief that cold has an adverse effect on the common cold.

Although in animals exposure to cold has been shown to increase both the frequency and severity of viral infections, such exposure has not been demonstrated to increase the susceptibility of man to infection with common-cold viruses. Studies published to date, however, have been performed with volunteers whose antibody status to the infecting virus was not known.

For the present study, 44 volunteers found to be free of antibody to rhinovirus type 15 were inoculated with purified stocks of this strain. Of these, 27 were exposed to cold at the time of inoculation and during incubation, illness, and recovery. The remaining 17, who served as the control group, were not exposed to cold.

To test the normal reaction to the cold devices used in the study, five additional volunteers, wearing light cotton shorts and undershirts, spent one and one-half hours in rooms with temperatures of 4° and 10°C (centigrade). Since the cold caused shivering which led to elevation of body temperature, adjustments were made to lower body temperature. These consisted of immersion in a water bath at 32°C for four to six hours and of wearing wool jackets in the 10°C room.

The subjective opinion of the volunteers was that the experience in the 4°C room was uncomfortable and comparable to the short-term chilling commonly encountered in nature. In contrast, when placed in a tank with 32°C water three days later, they found the experience comfortable.

Inoculation of the 44 subjects was done by small particle aerosol in 28, by nasal instillations of virus-containing fluids in 16. There was no difference in clinical response to the two methods.

Inoculated After Exposure

In one experiment, 9 of the 16 volunteers inoculated by nasal drops were infected at the end of exposure in the 4°C room. The other seven were not exposed to cold. Infection rates in both groups were similar and the illnesses were typical of the common cold. All the infected persons demonstarted early-high virus-shedding patterns. In each an eight-fold or greater rise in serum neutralizing antibody developed five weeks after inoculation. Titers in both groups were comparable.

In following experiments, six volunteers were placed in the 10°C room and seven in the cold bath on the morning after inoculation. Both exposed groups were compared to unexposed volunteers inoculated at the same time. Results were similar in all three groups. The frequency and severity of illness were not significantly greater in the group exposed to cold than in the unexposed volunteers. Furthermore, there was no increase in quantities of virus shed from the nasopharynx among volunteers exposed to cold. Antibody responses among those exposed were also similar to those not so exposed.

Clinical responses, virus-shedding patterns, and

antibody responses were also similar in two volunteers placed in the water bath on the first or second day of illness and two others inoculated at the same time but not exposed to cold.

Illnesses Similar

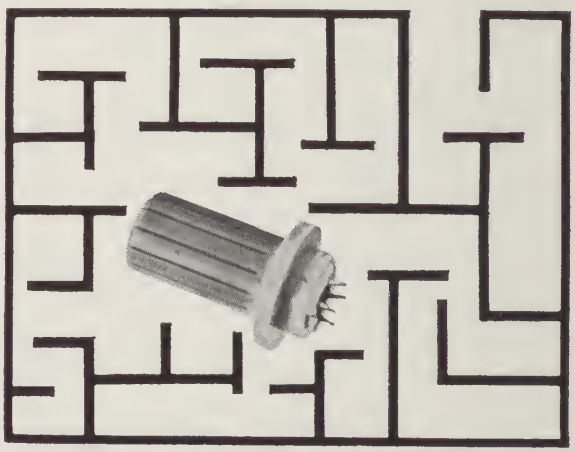
In another experiment, six volunteers were placed in the 10°C room and seven in the water bath on the seventh or eighth day after inoculation. Illnesses in the two groups were similar.

When four volunteers were re-exposed to cold in the water bath, nasal obstruction and discharge developed in three. In two, the symptoms disappeared within eight hours; in the third, who also had headache and cough, the symptoms lasted for 24 hours. No symptoms were observed in the three volunteers first exposed to cold after recovery from illness. Virus-shedding patterns and mean antibody responses were similar in both groups.

Pneumococci and staphylococci as well as nonpathogenic species of bacteria were recovered from nose and throat swabs from both the volunteers exposed to cold and from those not exposed in each of the experiments.

No effect of exposure to cold on a common cold due to rhinovirus type 15 that might account for the popular belief that cold was bad for a common cold was demonstrated. However, two possible mild effects of cold on rhinovirus illness were noted. One was a slight increase in nasal symptoms in three of seven volunteers exposed to cold during recovery, and the other was a slightly greater frequency of illness among some subjects exposed to cold during the incubation period. In both, the difference between subjects exposed to cold and the non-infected subjects in the control group was minimal.

Failure to demonstrate a relationship between cold and the common cold could be because environmental temperature has no effect on the common cold; or because exposure for longer periods or to more severe conditions may be necessary to influence the course of common colds. It may be, too, that exposure to cold influences the course of other viral illnesses in man, but not rhinovirus illness.



It is also possible that infection with a wild rhinovirus and its tissue culture progeny would have a different result, as might exposure to a different strain of virus. However, rhinoviruses are the most frequent isolates from adults with colds and, with the possible exception of type 1A, there are no predominant serotypes.

No Bacterial Complications

Exposure methods used in the study permitted testing of differing effects of cold. The 4°C room was analogous to short-term chilling of the type encountered in nature. The water bath was a comfortable procedure, but produced a fall in body temperature.

None of the volunteers had bacterial complications such as otitis media or pneumonia. The presence of potentially pathogenic organisms was not greater in the volunteers after infection and exposure to cold than in those after infection alone. In neither group were potential pathogens more frequent after infection than before inoculation. There was no evidence that respiratory viral infections predispose to pneumonia by qualitative changes in bacterial flora. More detailed bacteriologic studies will be needed to determine if significant quantitative changes occur in this regard.

Medical Librarianship Aids

In January we listed recent biographical and organizational directories received by the library, hoping to give both physicians and other associations, as well as paramedical personnel an idea of the scope and availability of this type of information. Now it seems appropriate to mention a few of the more recent works of a professional nature mainly, in the field of librarianship.

Medical Reference Works, 1679-1966, a selected bibliography: One of the outstanding bibliographic publications of the past few years. Edited by John B. Blake and Charles Roos, published by the Medical Library Association as MLA publication number 3, in 1967. This bibliography of more than 2,700 titles grew out of the need for a separate bibliography which could be revised as needed, independent of the *Handbook of Medical Library Practice.* Previously, the Handbook had included the bibliography, the first edition in 1943 having 1061 titles listed, the second, 1956 edition, having 1965 titles. The third edition is now in preparation and will carry the numbering and title of the original publication, but Medical Reference Works will start out anew.

The staff of the National Library of Medicine has worked long hours to perfect and complete this very helpful reference tool for the furtherance and improvement of library service to the medical profession.

The three main divisions of the contents are: General Medicine; History of Medicine; and Special subjects. General medicine is arranged by form, such as: indexes and abstracts, bibliographies, translations, periodicals, directories, and congresses. History and special subjects are arranged alphabetically. Entries are numbered 1-2703 and indexed accordingly.

Bibliographic information is good, with short annotations, but trade information such as price is omitted, as well as the explanation of the symbols indicating titles recommended for small libraries. An indispensable bibliography for any medical library.

Other titles of interest are:

Occupational Health Bookshelf: selected reference as recommended by the Industrial Medical Association (Reprinted from the Journal of Occupational Medicine, volume 10, number 8, August 1968). Arranged by subject.

Historical Review of Medical Libraries in Brooklyn by Helen Kovacs, Director, Downstate Medical Center, State University of New York, Brooklyn, New York.

An interesting short history of the various libraries involved in the culmination of the Downstate Medical Center and its satellites.

Outline for the organization of hospital libraries, by Beatrix A. Robinow, Biomedical Librarian, McMaster University, published by Canadian Medical Association, 1967. A very good elementary manual on organization of the hospital library. Bear in mind that information, such as prices, is given from the Canadian viewpoint and spelling follows the British rule.

Yale's Selective Book Retirement Program, prepared by Lee Ash, editor and research analyst. Archon, 1963.

A report of a 3-year project under a grant from the Council on Library Resources, Inc. Mr. Ash outlines this project with the objective of assisting other libraries in establishing a weeding, storage, and eventual book selection program. He included plans for actual physical storage and technical routines involved, as cataloging. Valuable to libraries planning similar programs.

* * *

Before annual meeting in April, send your special requests for subjects or titles to the library so they can be included in our exhibit.

NEW ACCESSIONS—BOOKS

(Arranged by author and title)

Abrahams, Harold J.
Extinct medical schools of nineteenths-century Philadelphia. Philadelphia, University of Pennsylvania Press, 1966.

Alderman, Alice J.
Prescribed and nonprescribed medicines: type and use of medicines. U. S. July 1964-June 1965. Washington, U. S. Dept. of Health, Education and Welfare, 1967.

American Heart Association Summer Workshop Denver, 1967.
Measurement of heart chamber volumes and dimensions, a summary of the proceedings of a summer workshop, sponsored by the Council on Basic Science of the American Heart Association July 24-27, Denver, Colorado. New York, American Heart Association, 1967.

Influenza 1968-69

Hong Kong influenza, that is, A2/HK/68 was first recognized in Maryland among the students of a Baltimore college during the week beginning November 25. The onset of this outbreak was during the second week in November. Since then, reports of increasing prevalence of the influenza-like illness have come in from all parts of the city and the state. The spread of the outbreak in the counties lagged a week or ten days behind Baltimore. It appears that the peak was reached in Baltimore city during the week beginning December 16 and in most of the counties during Christmas week. By the third week in January the outbreak was in a definite decline throughout the state, as evidenced by school and industry absenteeism which have almost without exception returned to normal for this season of the year. School authorities report the elementary school age groups have not been greatly involved and the attack rates were highest among young adults. It is interesting to note that the University of Maryland at College Park with 32,000 students, up to the time of its closing for the Christmas holidays, experienced no marked increase in upper respiratory illnesses. On the other hand, there were definite outbreaks in the Naval Academy in Annapolis, the University of Maryland Medical School, the personnel in the State Health Department, and in several industries.

The illness is characterized by the usual classical symptoms of influenza. Fever up to 104, headache, pharyngitis, myalgia were the chief symptoms. Lung involvement seemed to be less than in previous outbreaks. In many instances, complete recovery was slow. Although deaths from influenza and pneumonia have not been grouped by age, there is a preponderance in the upper age groups; and the weekly number of deaths for the whole state reached a record peak of 78 during the week ending January 12.

The presence of Hong Kong influenza virus was documented on November 30 both serologically and bacteriologically. Since then, the virus has been isolated from some 50 cases from Baltimore city, Anne Arundel, Baltimore, Charles, Prince Georges, Montgomery, and Frederick counties. No specimens have been examined from the Eastern Shore, although the disease was prevalent there during the latter part of December.

Anticipating a shortage of the monovalent A2/HK/68 vaccine, the Communicable Disease Division, in early November, advised all local health departments and state-administered hospitals to place orders through the Health Department for sufficient vaccine to immunize high-risk inmates and staff. On the basis of these requests, 12,000 doses were ordered and delivery made on December 5. This was immediately distributed to the various institutions. Unfortunately, some of the institutions failed to request the vaccine, and for this reason were not able to immunize until an additional supply was received on December 27. The shortage was nation-wide, and many physicians failed to obtain supplies before the second week in January. At the present time, the vaccine is available throughout the state.

Although the epidemic is on the wane, new cases will continue to occur for several weeks. As to whether or not there will be a recrudescence in the coming months is impossible to say. The Health Department is recommending, however, that all persons in the high-risk groups be given the Hong Kong vaccine.

KURT GORWITZ, ScD, STATISTICS DIRECTOR

Maryland State department of mental hygiene

Is There A Revolving Door?

Data from Maryland's five state-operated mental hospitals indicate that the concept that most alcoholics have a continuing series of admissions is not based on fact. During the year ending June 30, 1967, 3,690 persons had a total of 5,166 admissions to these facilities in which they received a primary diagnosis of alcoholism. Of these 3,690, 2,800 (or 75.9%) were hospitalized once during this 12-month period and 578 (or 15.7%) were admitted twice. Only 66 (or 1.8%) had five or more admissions. Further, 1,521 (or 41.2%) of all patients were admitted once during this year and had not been previously hospitalized in a psychiatric facility.

The distribution of these individuals by race, sex and number of admissions is shown in the following table:

	Total	White Male	White Female	Nonwhite Male	Nonwhite Female
Number of Admissions	5,166	3,349	481	1,176	160
Number of Persons Admitted	3,690	2,279	358	904	149
1 Admission	2,800	1,675	276	709	140
2 Admissions	578	374	58	139	7
3 Admissions	170	116	13	39	2
4 Admissions	76	56	7	13	–
5 Admissions	34	27	3	4	–
6 Admissions	17	17	–	–	–
7 Admissions	5	4	1	–	–
8 Admissions	6	6	–	–	–
9 Admissions	3	3	–	–	–
10 Or More Admissions	1	1	–	–	–
Rate *	163.3	242.2	36.7	548.8	87.0

* Number of persons admitted per 100,000 estimated population 18 years of age or older in specified race-sex group.

Proportionally, nonwhite rates were more than twice as high as comparable figures for both white males and females. In part, this was related to the greater availability and use by the latter group of alternate treatment resources. Also, Negroes have been hospitalized at an earlier stage of the illness. While 23.9% of the 904 nonwhite males were reported as acute alcoholics, 14.7% of the 2,279 white males received this diagnosis. Conversely, 64.9% of the nonwhite males and 77.1% of the white males were stated to be addicted to alcoholism. These figures appear to indicate varying incidence rates of the different levels of alcoholism as well as selective handling by police and other commitment sources.

Alcoholics are currently estimated to occupy one out of every nine state mental hospital beds and to account for a majority of all admissions. These figures represent a continuing, substantial increase in recent years. While it is not known whether or not these data reflect a growing total number of alcoholics, most of this rise in admissions for alcoholism has been concentrated in the age groups under 45. It would therefore appear that this upward trend will continue if present conditions persist. One possible alternative is the development of preventive programs, particularly among young state residents, concurrently with the large scale expansion of coordinated, community-centered treatment facilities.

Are Your Patient's Eyes Fit For Driving a Car?

SOLOMON E. BARR, MD
Silver Spring, Maryland

On today's high-speed highways the driver is pressed for quick reactions mile after mile, his eyes constantly shifting from the often poorly lit road ahead, to his instrument panel, to his rear view mirror. How well can he see? Until this past year the visual standards for Maryland drivers were the lowest in the United States.

The AMA Committee on Medical Aspects of Automobile Injuries believes that vision in one eye should be 20/40 or better.[1] Until July 1, 1968, people in our State received licenses to drive when vision was only 20/70 in the better eye. Over a period of years their vision may have further deteriorated but they may still have an unrestricted license. The new law requires that a driver must have vision in each eye of at least 20/40.[2] If he has only monocular vision, bilateral side mirrors must be employed. People with recent loss of vision in one eye are prohibited from driving for 90 days.[2]

For safe driving, a motorist must possess some lateral perspective in order to pass other vehicles or to see people or machines approaching from the side. A visual field of 140° or better is required.[1] Dark adaptation and susceptibility to glare are of great importance in night driving. Of course, dark glasses should not be worn at night and the windshield not tinted more than one-third from the top. At the present time, because of standardization of traffic lights, it is doubtful that color blindness is of great consequence.[1]

People should have their eyes checked regularly, and the Department of Motor Vehicles should know about drivers who are almost blind. Correct glasses must be worn and any necessary extra mirrors affixed to the car. We physicians can play a role in the reduction of traffic accidents by "seeing" that our patients see well enough to drive.

———O———

From the Subcommittee on Traffic Safety of the Medical and Chirurgical Faculty of the State of Maryland

Medical Building Planned For North Avenue Site

Madison Park Professional Center, Inc., a newly formed corporation sponsored by nine Baltimore doctors, has announced plans to build a medical center on the northeast corner of North Avenue and Eutaw Place in the Madison-Park North Urban Renewal Area.

The center, a one-story L-shaped building, will face the North Avenue, Eutaw Place corner and offer ground-level pedestrian access through a landscaped plaza to medical suites for eight physicians and two dentists, a medical laboratory and an ethical pharmacy.

Completion of the center is anticipated by this spring.

The sponsors of the new corporation and its building venture are: William R. Birt, MD, Herbert Garland Chissell, Jr., MD, John T. Chissell, MD, Raymond L. Gray, DDS, Claude D. Hill, MD, Benjamin J. Kimbers, Jr., DDS, Archie Robinson, Jr., MD, Oakley H. Saunders, MD, and Richard Tyson, MD.

ETHICS CORNER

Some physicians have raised the question as to whether they may charge interest on overdue accounts. In fact, some printers of physicians' bills have made this suggestion to physicians.

The AMA's code of ethics provides that physicians should derive their income solely from the rendering of professional services. In addition, the same code indicates that physicians should not impose undue hardship on patients when they fail to pay their bill within a prescribed period of time.

The specific statement reads:

"It is not in the best interest of the public or the profession to charge a penalty if fees for professional services are not paid within a prescribed period of time, nor is it proper to charge a patient a flat collection fee if it becomes necessary to refer the account to an agency for collection."

Part of the same Judicial Opinion reads as follows:

"Since the practice of medicine is a profession and not a business, the practices adopted by businesses are not necessarily suitable."

WE PRESCRIBE FOR DOCTORS:

Hot under the collar...

high under the cuff.

Sometimes
he forgets he has hypertension, gets hot under the collar...high under the cuff.

For such patients, consider **Regroton®**

chlorthalidone	50 mg.
reserpine U.S.P.	0.25 mg.

To lower blood pressure
and allay anxiety in hypertension.

For brief summary of prescribing information, see next page.

RE-6392

Regroton®

Geigy

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

the once-a-day tablet for anxious hypertensives

Regroton is a combination of two basic antihypertensives designed to lower blood pressure and allay anxiety in hypertension. With Regroton he can keep his shirt on and you can keep his blood pressure down.

Before prescribing, please review carefully the indications, contraindications, warning, precautions, adverse reactions and dosage information below.

Regroton®
Each tablet contains:
chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

Indications: Hypertension.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs.
Use in pregnancy: Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. Increased respiratory secretions, nasal congestion, cyanosis and anorexia may occur in infants born to reserpine-treated mothers.
Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue therapy with this agent two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.
Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Severe salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients.
Adverse Reactions: The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible.
Average Dosage: One tablet daily with breakfast.
Availability: Pink, single-scored tablets in bottles of 100 and 1000. (B)46-600-C

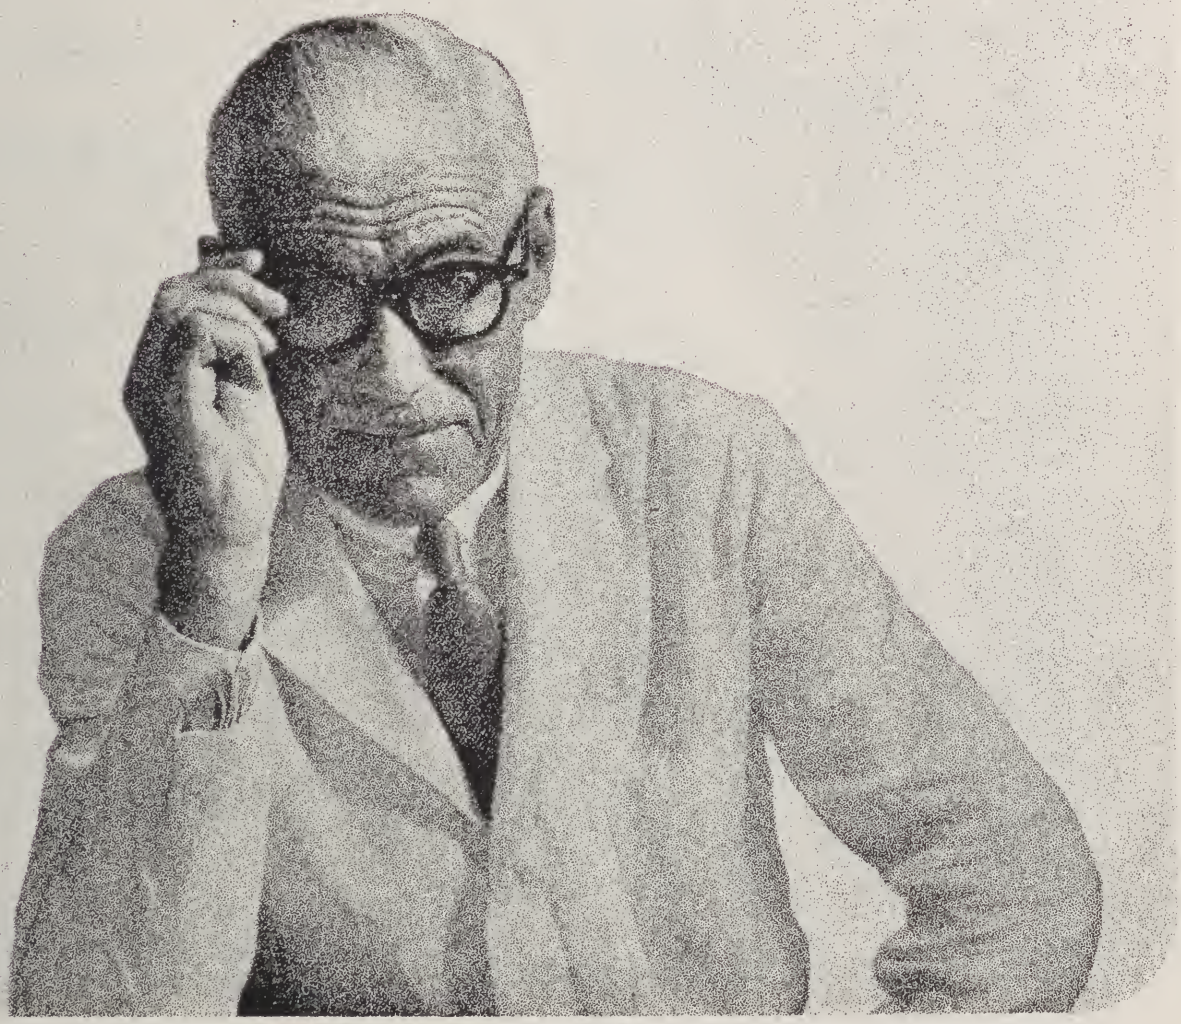
RE-6392

the "Action" gap

Of the more than 100 different types of cancer, colon and rectal cancers are unique for two compelling reasons:



High incidence:	Annual new cases number about 73,000. Deaths now total 46,000 a year.
High curability potential:	Early diagnosis and prompt treatment could save almost 75%. Survival rate is now only 44%.

How to close the critical gap between possible and actual survivals?

The "procto" can today help save more lives from cancer than any other step in the checkup. Which is why, in our constant emphasis on the importance of annual checkups, we urge the inclusion of a "procto" ...and make available films and other pertinent materials for the layman and the physician. We *are* closing the "communications" gap.

Joint action by people and their doctors can help close the "action" gap to reach a cure rate of almost 75% for colon and rectal cancer.

EXAM TABLE—Hematrocrit & EKG machines, ice box, scale, microscope, autoclave, and furniture. Almost new. Write to: Box #8, c/o JOURNAL, 1211 Cathedral St., Balto., Md. 21201.

"Truth" in Cigarette Packaging

America's physicians are overwhelmingly in favor of strengthening the health caution on cigarette packages and are for stricter control of cigarette advertising.

Their feelings, announced as the result of a recent Marion Laboratories Playback Poll, are in substantial agreement with the American Cancer Society, the Federal Trade Commission, and the U. S. Public Health Service, which are attempting to influence the Congress to pass laws which would put stricter curbs on cigarette labeling and advertising.

This poll includes the opinions of 1,156 doctors across the country.

Seventy-six percent of all the doctors polled—and 85% of the cardiologists—favored the stricter cigarette controls, while only 17% disagreed.

These findings are in close agreement with a poll conducted by the American Cancer Society, which found that 66% of the public agreed that a health warning should be required in cigarette advertising, while 48% were for stronger words in the health caution in cigarette packages.

Information for Authors

MANUSCRIPTS: Manuscripts will be accepted for consideration for publication with the understanding that they are original, have never before been published, and are contributed solely to the Maryland State Medical Journal.

All manuscripts are acknowledged upon receipt and are followed up by notification of either acceptance or rejection. Rejected manuscripts are returned by regular mail. Accepted manuscripts become the property of the Journal and are not returned. The Journal is not responsible for loss of manuscripts through circumstances that are beyond its control.

Manuscripts should be addressed to: Editor, Maryland State Medical Journal, 1211 Cathedral St., Baltimore, Md. 21201.

SPECIFICATIONS: Manuscripts must be original typed copy, doublespaced throughout (Including text, case reports, legends, tables and references) with margins of at least 1½ inches. Pages should be numbered consecutively.

The manuscript should include the title (brief and concise), the full name of the author (or authors) with degrees, academic and professional titles, affiliations, and any institutional or other credits. Please include a complete address where the author may receive proofs of his article for his approval and corrections.

All manuscripts should be accompanied by a carbon or Xerox copy and the author should retain another copy for his records.

TABLES: Each table should be typed on a separate sheet of paper, be numbered, have a brief descriptive title, and its position in the text should be indicated.

Be sure that statistics are consistent in both tables and text.

REFERENCES: References should be limited to those citations noted in the text, and kept to a minimum of 18. (A complete review of the literature is rarely desirable.) The references must be typed, doublespaced, and are to be numbered consecutively as they appear in the text, with their positions in the text indicated. An alphabetized bibliography is used only when the listing is of books suggested for supplementary reading.

All references must be checked for absolute accuracy. Each journal reference must include author(s) and initials, complete title of article, name of publication, volume, first page of article, and date. Complete dates (month, day, and year) are to be included with all references that have appeared within the last three years. Include with book references name of author(s) and/or editor(s) with initials, title of book, edition, location, publisher, year, volume (if given), and page. If reference is to a chapter within a book, include the author of the chapter (if different from author of the book), and the title of the chapter, if any.

ILLUSTRATIONS: Authors are urged to use the services of professional illustrators and photographers when possible. Drawings and charts should always be done in black ink on white paper. Clear, glossy photographs, black on white, should be submitted and such illustrations numbered consecutively and their positions indicated in the text.

Magnifications will be modified in proportion to the amount of reduction necessary to fit the pages of the Journal. Please do not deface an illustration by writing on the front or the back, nor should it be taped or pasted to paper. The illustration may be pasted onto a piece of cardboard. Attached to the back of each illustration, chart or photograph should be the figure number, the author's name and the title of the article.

Legends for illustrations should be typewritten on a separate page with numbers corresponding to those on the photographs and drawings.

Recognizable photographs of patients are to be masked and should carry with them written permission for publication.

EDITORIAL RESPONSIBILITY: Manuscripts are subject to editorial modification and such revisions as are necessary to bring them into conformity with Journal style.

Statements made or opinions expressed by any contributor in any article or feature published in the Journal are the sole responsibility of the author.

PERMISSIONS: When material is reproduced from other sources, full credit must be given to both the author and publisher and written permission from these sources must be included when the material is submitted.

COPYRIGHT: Material that is published in the Maryland State Medical Journal is protected by copyright and may not be reproduced without the written permission of both the author and the Journal.

from the discord of anxiety...

to emotional harmony

with the aid of antianxiety

Librium®
(chlordiazepoxide HCl)

5-mg, 10-mg and 25-mg capsules

In an age of swift change and challenge, susceptible individuals may experience varying degrees of excessive anxiety. The resulting emotional stress may precipitate significant functional disorders or complicate existing organic disease. In properly individualized maintenance dosage, Librium (chlordiazepoxide HCl) quickly helps relieve anxiety and apprehension, provides useful adjunctive therapy in psychophysiologic disorders—yet seldom impairs mental acuity or ability to function. Librium has demonstrated a wide margin of safety in short- and long-term therapy.

Also available:

Libritabs®
(chlordiazepoxide)

ROCHE
Roche
LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Indicated when anxiety, tension and apprehension are significant components of the clinical profile.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (e.g., excitement, stimulation and acute rage) have been reported in psychiotric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulacytasis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

VOLUME 18 APRIL 1969 NUMBER 4

CONTENTS:

Editorial—The Age of Aquarius 46
"The stars impel, they do not compel!
What you make of your life is largely up to you."

The Adolescent Patient: An Overview, Sheldon D. Glass, MD 48
"The 20th Century Adolescent is a topic which in recent years has stirred the interest and demanded the attention of the entire nation. We have had overt rebellion from our adolescents. They are demanding IN. They want a piece of the action."

Implications of the Sex Revolution in the Adolescent's Search for Sexual Identity, James F. Masterson, Jr., MD 53
"Perhaps the main implication of the sexual revolution is the fact that the topic is mentioned almost always in the course of everyday conversation. . . . Everyone has, or had, sexual conflicts in his development which he resolved to, perhaps, a relative degree. Still, he wants to know more about them. . . ."

Addiction, Psychodelic Experimentation and Abuse of Drugs by the Concerned Generation, Dale G. Friend, MD 59
"There have been discoveries of new (drug) substances in recent times. . . . The very nature of the action of these drugs makes it difficult to develop a true assessment of their action. It is very easy to be misled as to the effect. . . . For example, claims made by certain groups, that smoking dried banana pulp or peels gives a psychological effect, are without foundation. Such could either be a delusion resulting from a placebo effect, or a hoax put on the squares by the hippies."

Depression in Adolescents and College Students, Francis J. Braceland, MD, and Dana L. Farnsworth, MD 67
"Despite the fact that depression has been recognized for over two thousand years and is the psychiatric diagnosis most frequently made today, there is much about it that remains enigmatic."

ON THE COVER: When the term adolescent crops up in conversation these days, we usually expound on the negative aspects of the group. Even though all young adults are not rebellious, dirty, sloppy and addicted to drugs, the problems presented by the speakers at the Geigy Symposium on the 20th Century Adolescent (pp 48-73) are those which are, and have been, most readily observed. Photograph by Frank Spinek, courtesy of the News American.

When he needs an antibiotic
he may be a candidate for

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

b.i.d.

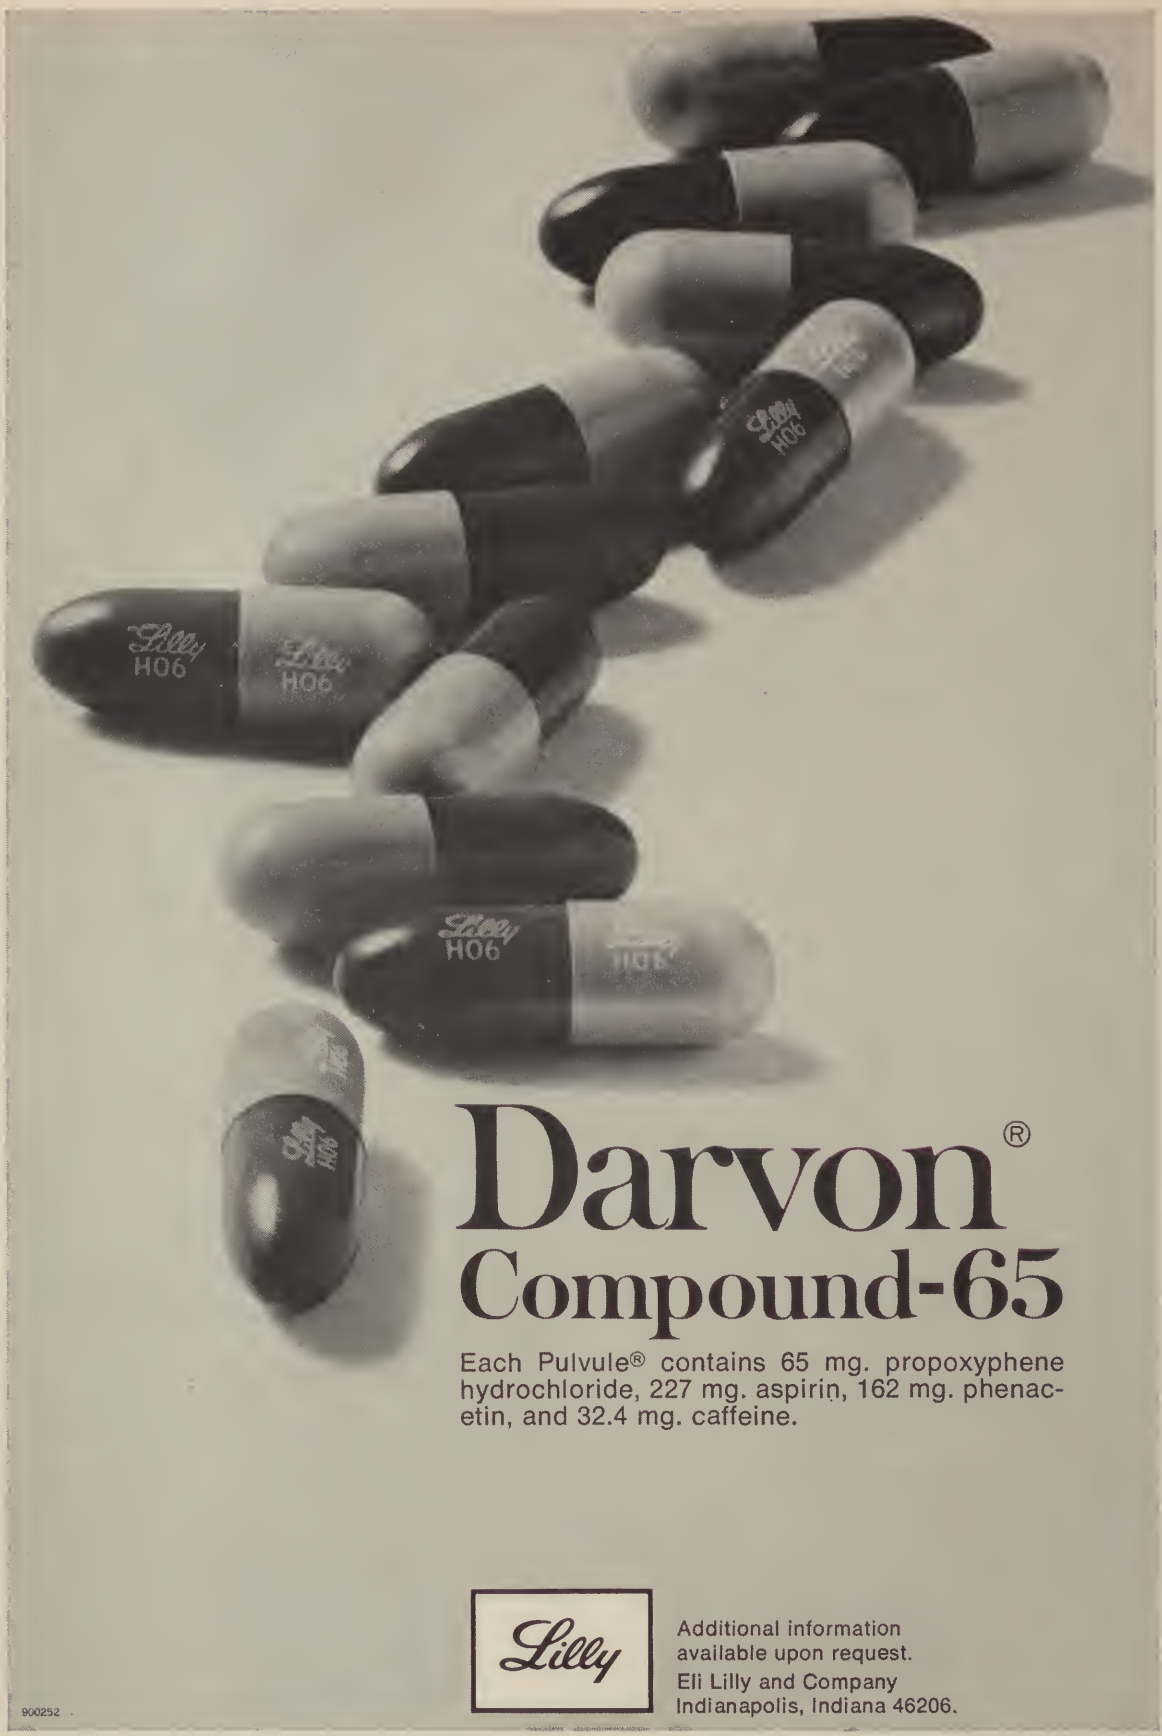
To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Effectiveness: Because its antibacterial component is DECLOMYCIN Demethylchlortetracycline, DECLOSTATIN should be equally or more effective therapeutically than other tetracyclines in infections caused by tetracycline-sensitive organisms. The antifungal component, Nystatin, protects against superinfection by antibiotic-resistant fungal overgrowth (particularly monilia) in the intestinal tract.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.



Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes; a rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs, discontinue medication and institute appropriate therapy. Demethylchlortetracycline may form a stable calcium complex in any bone-forming tissue with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

With the broad Polycillin (ampicillin trihydrate) spectrum...

...you have a lot going for you in the wide range of bacterial infections.

PRESCRIBING INFORMATION. For complete information consult Official Package Circular.
Indications: Infections due to susceptible strains of Gram-negative bacteria (including Shigellae, *S. typhosa* and other Salmonellae, *E. coli, H. influenzae, P. mirabilis, N. gonorrhoeae* and *N. meningitidis*) and Gram-positive bacteria (including streptococci, pneumococci and nonpenicillinase-producing staphylococci).
Contraindications: A history of allergic reactions to penicillins or cephalosporins and infections due to penicillinase-producing organisms.
Precautions. Typical penicillin-allergic reactions may occur, especially in hypersensitive patients. Mycotic or bacterial superinfections may occur. Experience in newborn and premature infants is limited and caution should be used in treatment, with frequent organ function evaluations. Safety for use in pregnancy is not established. In gonorrheal therapy, serologic tests for syphilis should be performed initially and monthly for 4 months. Assess renal, hepatic and hematopoietic function intermittently during long-term therapy.
Adverse Reactions: Skin rash, pruritus, urticaria, nausea, vomiting, diarrhea and anaphylactic reactions. Mild transient elevations of SGOT or SGPT have been noted. Black tongue has been noted in some patients receiving the Chewable Tablets.
Usual Dosage: Adults—250 or 500 mg. q. 6 h. (according to infection site and offending organisms). Children—50-100 mg./Kg./day in 3 to 4 divided doses (depending on infection site and offending organisms). Bacterial meningitis —150-200 mg./Kg./day in 6 to 8 divided doses. Children weighing more than 20 Kg. should be given an adult dose when prescribing orally. In parenteral administration, children weighing more than 40 Kg. should be given an adult dose. Beta-hemolytic streptococcal infections should be treated for at least 10 days.
Supplied: Capsules—250 mg. in bottles of 24 and 100. 500 mg. in bottles of 16 and 100. For Oral Suspension—125 mg./5 ml. in 60, 80 and 150 ml. bottles. 250 mg./5 ml. in 80 and 150 ml. bottles. Chewable Tablets—125 mg. in bottles of 40. Injectable—for I.M./I.V. use—vials of 125 mg., 250 mg., 500 mg., and 1 Gm. Pediatric Drops—100 mg./ml. in 20 ml. bottles.

EUROPEAN TRIPS PLANNED

Two European trips have been planned for the spring and fall of 1969. A trip to Vienna is scheduled for May 12 to May 18; and a trip to Spain for October 12 to October 21.

Full details may be obtained from Travel Guide Agency, 416 N. Charles Street, Baltimore, Md., 21201, or telephone SA 7-0682, Mrs. Beverly Wolins.

COMPLETION OF INSURANCE CLAIM FORMS

Physicians and their office assistants are urged to use caution in completing insurance claim forms. In the space provided for the physician's usual and customary fee, that charge should appear - - NOT THE AMOUNT ALLOWED BY THE CARRIER.

NAME CHANGE

The Baltimore Dermatological Society has officially changed its name to the Maryland Dermatological Society.

Current officers are:

Joseph W. Burnett, MD, President
M. Eugene Tudino, MD, Secretary-Treasurer

COMMISSION ON MEDICAL DISCIPLINE

Physicians are reminded that the Commission on Medical Discipline takes effect July 1, 1969. Guidelines for physicians in connection with the Commission are in the mail.

Any questions on the Commission should be directed to the Faculty office.

JCAH ACCREDITATION STANDARDS

Accreditation standards for the Joint Commission on Accreditation of Hospitals are presently under review. Preliminary revisions are now under study by a joint committee of the AMA and JCAH.

Two meetings have been held at which State Medical Society representation has been requested. Individuals from Maryland who have attended both sessions are Manning W. Alden, MD, Annapolis, Vice-chairman of the Faculty's Council; and Richard D. Bauer, MD, Adelphi, Past-president.

JCAH ACCREDITATION STANDARDS (cont'd)

Individuals interested in the revised standards or who wish to comment on them are urged to contact either of these two physicians.

LABORATORY BILLING RULING

In late February, Blue Shield indicated in a ruling that payment would not be made to physicians for services such as the drawing of blood or other specimens, indicating that the charge for such services are included in the physician's normal office visit fee.

The Faculty's Executive Committee has determined that the ruling adopted by the Council in June, 1965, is still applicable. The ruling is as follows:

"If a clinician and a laboratory share the responsibility for a laboratory procedure, each should send a bill for services rendered. No physician should be denied a reasonable fee for obtaining a specimen for testing purposes and/or interpreting the results of the test, but this should be itemized separately and appear on the physician's statement."

MED-CHI RETIREMENT FUND

The net asset value of the Med-Chi Members Retirement Fund has increased 19.09% for the period January 1, 1968, through December 31, 1968.

OSTEOPATHS

The Faculty office has been receiving an increasing number of inquiries regarding Osteopaths and the acceptance of such individuals who are licensed to practice medicine and surgery in Maryland. Briefly, the situation is as follows:

1. Such individuals can be accepted into medical society membership if eligible under the same standards applicable to Doctors of Medicine.

2. Such persons can be accepted into internship or residency training if either licensed in Maryland as indicated; or if they would be eligible for such licensure on completion of their training.

If further details are needed, please contact the Facuy office.

FRANK BILLINGS, Edwin F. Hirsch, MD; published under the auspices of the Chicago Medical Society by the Printing Department, University of Chicago, 1966.

This biography of Dr. Frank Billings covers the entire span of his career and includes two brief commentaries on outstanding personalities known by the physician.

Dr. Billings was primarily responsible for the fusing of teaching medical students at Rush Medical College and the University of Chicago. He was well-known as an educator, innovator, and physician.

COOKING FOR YOUR CELIAC CHILD, Charlotte Baum Sheedy and Norman Keifetz; The Dial Press, New York, 1969.

This is the only gluten-free cookbook written to aid the parents of celiacs in preparing appetizing meals the whole family can enjoy eating together—and recipes for foods (using safe ingredients) which children most want and which are, in the usual composition, prohibited in a celiac's diet.

In addition to the over 300 specially developed and tested recipes, the authors have prepared a chapter, helpful to doctors and reassuring to parents, containing a full medical description of the disorder (including what is and what is not known about it), special psychological problems parents may encounter and how to deal with them, why and how to use the book. The book also contains lists of permitted and forbidden foods, recommended brand products found at supermarkets, sources for special health foods and foreign products, conversion tables for gluten-free cereal grains and flours and their equivalencies and characteristics, and a selected medical bibliography on the litrature in the field.

NURSES CAN GIVE AND TEACH REHABILITATION, A Manual by Mildred J. Allgire, RN, RPT, MA; the Springer Publishing Company, New York, 1968.

This paperback booklet describes the needs, values, procedures, and equipment needed for restoration of the disabled person so that he can make use of every ability that remains after illness or injury. It is the second edition, the publication of which was encouraged by the highly favorable acceptance of the first edition.

The fundamentals of care, effective for all age groups are covered, and the book points up the principles involved so that application may be found in almost any situation in the hospital or the home.

PHYSIOLOGY OF THE GASTROINTESTINAL TRACT, E. Clinton Texter, Jr., MD, Ching-Chung Chou, MD, Higino C. Laureta, MD, and Gaston R. VanTrappen, MD; The C. V. Mosby Company, St. Louis, 1968.

This is one in a series of coordinated texts dealing with body-system physiology, with which it is hoped there are some advantages. These books are oriented toward the medical student, their goal being to present current concepts of physiology.

In this present volume, the areas of physiological knowledge most relevant to medical practice are delineated. It is well-presented, and while directed toward the medical student, it would do no harm for the busy practitioner to read it and update himself in many ways.

CURRENT CONCEPTS IN ANESTHESIOLOGY, John Adriani, MD; The C. V. Mosby Co., St. Louis, 1968.

In recent years, anesthesiology has broadened its scope to encompass many subjects, such as the pharmacology of adjunctive anesthetic drugs, the hazards of drug interactions, and various phases of physiology, all of practical importance to the anesthesiologist.

These presentations are not exhaustive reviews that completely summarize all of the literature on a particular subject. They have been prepared by clinicians, written in clinicians' language and terminology, and intended primarily for clinicians.

(Continued next page)

TODD-SANFORD CLINICAL DIAGNOSIS BY LABORATORY METHODS, 14th ed., Israel Davidsohn, MD, and John Bernard Henry, MD; W. B. Saunders Co., Philadelphia, 1969.

The 14th edition of *Clinical Diagnosis by Laboratory Methods* aptly illustrates the advances which have taken place in the field of clinical pathology in the past 61 years. The first edition, written in 1906, by Dr. James C. Todd, *A Syllabus of Lectures Upon Clinical Diagnosis,* was only 124 pages and at the time, considered fairly complete and topical. The current text has expanded to 1,308 pages and is wanting in several areas. Gone is the era when the clinical pathologist was known as a physician technician —who worked from "a single kitchen table with a few shelves and a few bottles, screened off in a corner of the office, which sufficed for a laboratory."

The expanding field of clinical pathology has necessitated multiple contributors, in this case, 29 different experts from the fields of pathology, microbiology, clinical medicine, and laboratory medicine, to compile a text of this excellent stature.

The opening two chapters on the microscope and statistical tools in clinical pathology contain just enough highlights to be informational and to act as a backdrop for the remainder of the book. They are by no means meant to be complete in the areas that they cover. It would have seemed more logical to place the chapter on clinical chemistry (Chapter 10) next in sequence of the book because it is here that the basis of specimen collection and processing, mathematics, chemical calculations and basic laboratory techniques are discussed, which is basic to the remainder of the book.

The chapters which are best covered are those on blood, tests of hepatic function, serum enzyme deterioration, gastric and duodenal contents.

Examination of urine and renal function studies were well-done from the coverage of laboratory tests, but a bit brief as regards the application to clinical entities.

The sections on medical microbiology, protozoology, and mycology are excellent for rapid reference to simplified methods needed to accurately define the nature of common clinically encountered microorganisms.

The chapter on seminal and amniotic fluids are concise and well-written. Enough information is given for the clinical physician to apply the laboratory results of these areas with a minimal background of material.

In general, this book offers an excellent review for those physicians in clinical medicine who have a laboratory problem. It is a ready reference and presents an explanation of the laboratory studies and a brief review of the clinical possibilities. It is not a complete compendium or encyclopedia for any of the subjects covered. Anyone desiring more detailed information would have to refer to more complete textbooks on hematology, internal medicine, or endocrinology.

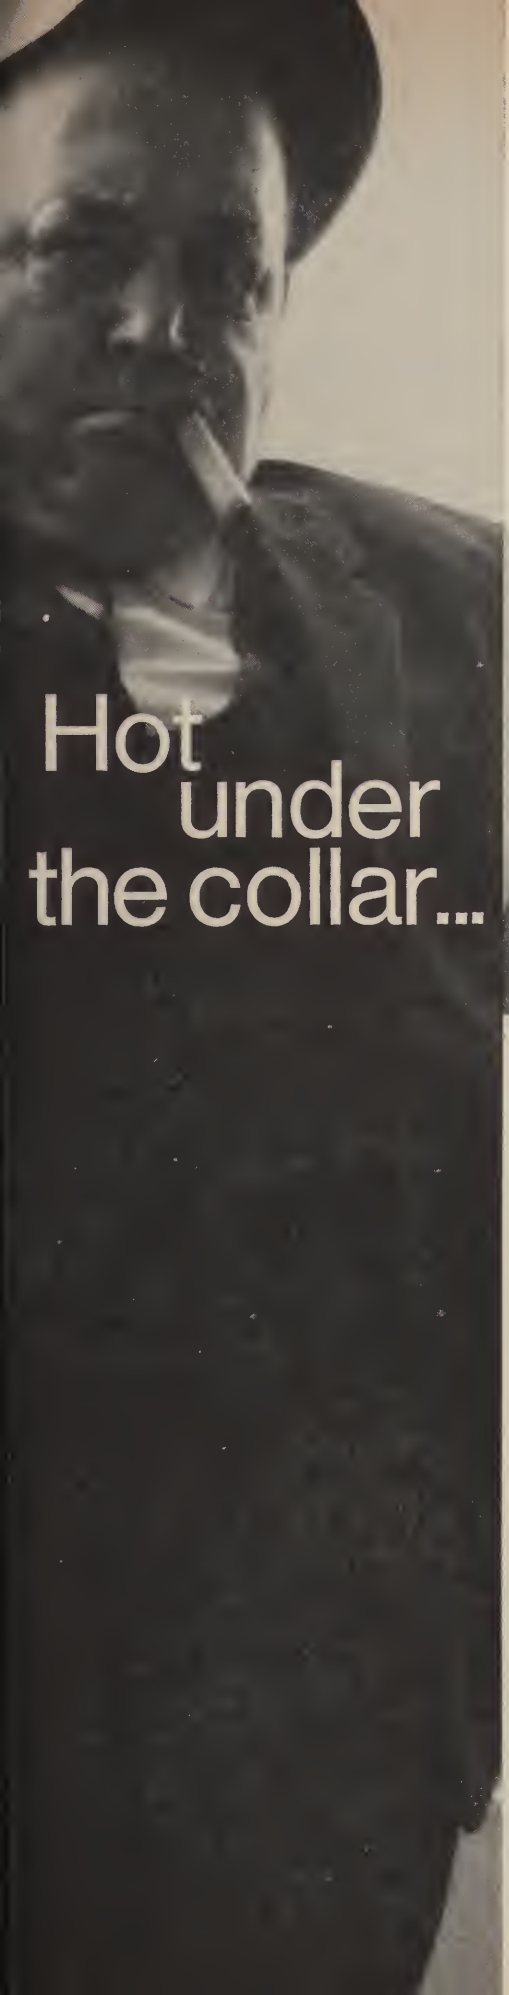
the thousandth teaspoonful

Peptic ulcer patients find the thousandth dose of this antacid as effective and easy-to-take as the first!

Optimal neutralization[1] — provided by the combination of aluminum and magnesium hydroxides.

Unfailing good taste — confirmed by 87.5% of 104 patients in one study, after a total of 20,459 documented days on Mylanta Liquid or tablets.[2]

Concomitant relief of G. I. gas distress — provided by the proven antiflatulent action of simethicone[3].



Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth); one or two teaspoonsful to be taken between meals and at bedtime, or as directed by physician.

Hot under the collar...

high under the cuff.

Sometimes
he forgets he has hypertension, gets hot under the collar...high under the cuff.

For such patients, consider **Regroton®**

chlorthalidone	50 mg.
reserpine U.S.P.	0.25 mg.

To lower blood pressure
and allay anxiety in hypertension.

For brief summary of prescribing information, see next page.

RE-6392

Regroton®

Geigy

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

the once-a-day tablet for anxious hypertensives

Regroton is a combination of two basic antihypertensives designed to lower blood pressure and allay anxiety in hypertension. With Regroton he can keep his shirt on and you can keep his blood pressure down.

Before prescribing, please review carefully the indications, contraindications, warning, precautions, adverse reactions and dosage information below.

Regroton®
Each tablet contains:
chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

Indications: Hypertension.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs.
Use in pregnancy: Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. Increased respiratory secretions, nasal congestion, cyanosis and anorexia may occur in infants born to reserpine-treated mothers.
Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue therapy with this agent two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.
Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Severe salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients.
Adverse Reactions: The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible.
Average Dosage: One tablet daily with breakfast.
Availability: Pink, single-scored tablets in bottles of 100 and 1000. (B)46-600-C

"the Donnatal® Effect"

	each tablet, capsule or 5 cc. of elixir (23% alcohol)	each Donnatal No. 2	each Extentab®
yoscyamine sulfate	0.1037 mg.	0.1037 mg.	0.3111 mg.
tropine sulfate	0.0194 mg.	0.0194 mg.	0.0582 mg.
yoscine hydrobromide	0.0065 mg.	0.0065 mg.	0.0195 mg.
henobarbital	(¼ gr.) 16.2 mg.	(½ gr.) 32.4 mg.	(¾ gr.) 48.6 mg.

(Warning: may be habit forming)

Brief Summary. Blurring of vision, dry mouth, difficult urination, and flushing or dryness of the skin may occur on higher dosage levels, rarely on usual dosage. Administer with caution to patients with incipient glaucoma or urinary bladder neck obstruction. Contraindicated in acute glaucoma, advanced renal or hepatic disease or a hypersensitivity to any of the ingredients.

A. H. ROBINS COMPANY, RICHMOND, VIRGINIA 23220

A·H·ROBINS

Two ways to provide your patients with a month's therapeutic supply of Vitamin C:

290 tangerines or 30 Allbee® with C.

Your patient would have to peel and eat 290 tangerines a month, almost 10 every day, to get as much Vitamin C as is contained in just one bottle of 30 Allbee with C capsules (taken one capsule daily). In addition, each capsule provides full therapeutic amounts of the B-complex vitamins. For example, as much niacin as 2 pounds of sirloin steak. This handy bottle of 30 Allbee with C capsules gives your patient a month's supply at a very reasonable cost. Also the economy size of 100. Available at pharmacies on your prescription or recommendation.

APRIL 25, 1969—12:30 P.M.

MALIGNANCIES OF THE CENTRAL NERVOUS SYSTEM

John A. Wagner, MD
Professor of Neuropathology
University of Maryland School of Medicine

The subject of intracranial tumor is reviewed with appropriate clinical-pathologic correlation. The salient features of the more important primary and secondary tumors is reviewed. Included also are notes on pathogenesis, relation to trauma and present status of research.

Sponsor: Frederick Memorial Hospital
Replays: Monday, April 28, 1969 12:30 P.M.
Wednesday, April 30, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

MAY 2, 1969—12:30 P.M.

CARCINOMA OF THE THYROID

Joseph B. Workman, MD
Associate Professor of Medicine
University of Maryland School of Medicine

Current knowledge concerning the causes, clinical classifications and methods of therapy in thyroid carcinoma will be discussed. Emphasis will be placed on the effect of age at onset, pathologic type, duration of disease and type of therapy upon eventual outcome.

Sponsor: Peninsula General Hospital
Replays: Monday, May 5, 1969 12:30 P.M.
Wednesday, May 7, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

MAY 9, 1969—12:30 P.M.

DIABETES

Thaddeus E. Prout, MD
Associate Professor of Medicine
The Johns Hopkins University School of Medicine, and Chief of Medicine,
Greater Baltimore Medical Center

Diabetes calls for long term management and a cooperative effort between patient and physician. The clinical problems encountered in the management of the diabetic is the subject of this presentation. Both prevention and therapy will be considered.

Sponsor: Washington County Hospital
Replays: Monday, May 12, 1969 12:30 P.M.
Wednesday, May 14, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

(Continued next page)

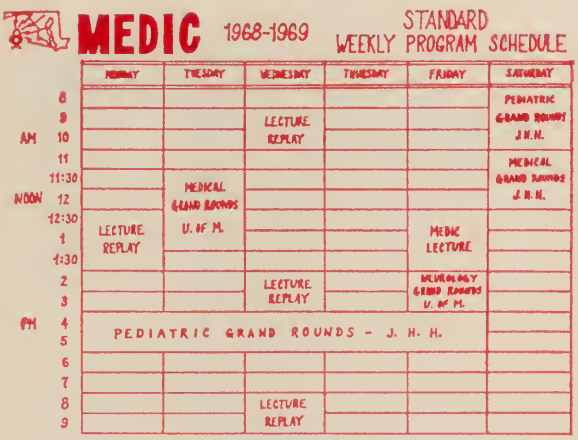
MAY 16, 1969—12:30 P.M.

HYPOTHYROIDISM

John G. Wiswell, MD
Associate Professor of Medicine
University of Maryland School of Medicine

A discussion of etiologic factors, unusual manifestations, and the indications for the various types of preparations used in treating hypothyroidism. The management of a patient with myxedema coma will also be discussed.

Sponsor: Anne Arundel General Hospital
Replays: Monday, May 19, 1969 12:30 P.M.
Wednesday, May 21, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.



MAY 23, 1969—12:30 P.M.

CANCER RESEARCH

Nathaniel I. Berlin, MD
Clinical Director National Cancer Institute
National Institutes of Health,
Bethesda, Maryland

Cancer research will be reviewed from three standpoints. Etiology, especially our current understanding of viral etiology. New diagnostic applications, principally in cytology and mammography. Therapeutic research oriented towards where we stand with various modalities.

Sponsor: Frederick Memorial Hospital
Replays: Monday, May 26, 1969 12:30 P.M.
Wednesday, May 28, 1969
9:00 A.M., 2:00 P.M., 8:00 P.M.

The AMBAR SCRAPBOOK of

Obesity Oddities

FACT & LEGEND

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg., phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety...helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

A. H. ROBINS COMPANY, RICHMOND, VA. 23220

A·H·ROBINS

You've made it one of your specifics in acute otitis media

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

You've made it one of your specific in acute otitis media

DECLOMYCIN acts against many strains of H. influenzae, pneumococci and streptococci, the most common invaders. In otitis media, where it is difficult to isolate the causative organism, this coverage may be important. However, some strain may be resistant and other pathogens can be involved.

You've found the high serum levels of DECLOMYCIN important, too. Its prolonged actio permits convenient 300 mg b.i.d. or 150 mg q.i.d. administration.

When specimens are obtainable, your culture studies will indicate the usefulness of DECLOMYCIN.

Effectiveness: DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines in infections caused by organisms sensitive to the tetracyclines.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocoli pruritus ani. Skin—maculopapular and erythematous rashes; a r case of exfoliative dermatitis has been reported. Photosensitivi onycholysis and discoloration of the nails (rare). Kidney—rise in BU apparently dose-related. Transient increase in urinary output, son times accompanied by thirst (rare). Hypersensitivity reactions—u caria, angioneurotic edema, anaphylaxis. Teeth—dental staining (y low-brown) in children of mothers given this drug during the latter h of pregnancy, and in children given the drug during the neonatal pe od, infancy and early childhood. Enamel hypoplasia has been seer a few children. If adverse reaction or idiosyncrasy occurs, discontir medication and institute appropriate therapy. Demethylchlortet cycline may form a stable calcium complex in any bone-forming tiss with no serious harmful effects reported thus far in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Sho be given 1 hour before or 2 hours after meals, since absorption impaired by the concomitant administration of high calcium conte drugs, foods and some dairy products. Treatment of streptococ infections should continue for 10 days, even though symptoms h subsided.

DECLOMYCIN®
DEMETHYLCHLORTETRACYCLINE

Capsules: 150 mg; **Tablets:** film coated, 3 mg, 150 mg and 75 mg of demethylchlorte cycline HCl.

A "cold" fact

NTZ® delivers relief of nasal symptoms

The *first spray*—1 or 2 squirts—of NTz opens the inferior part of the common meatus. The *second spray*, a few minutes later, shrinks the turbinates to promote adequate sinus drainage and ventilation—to help prevent sinusitis. Dosage may be repeated every three or four hours.

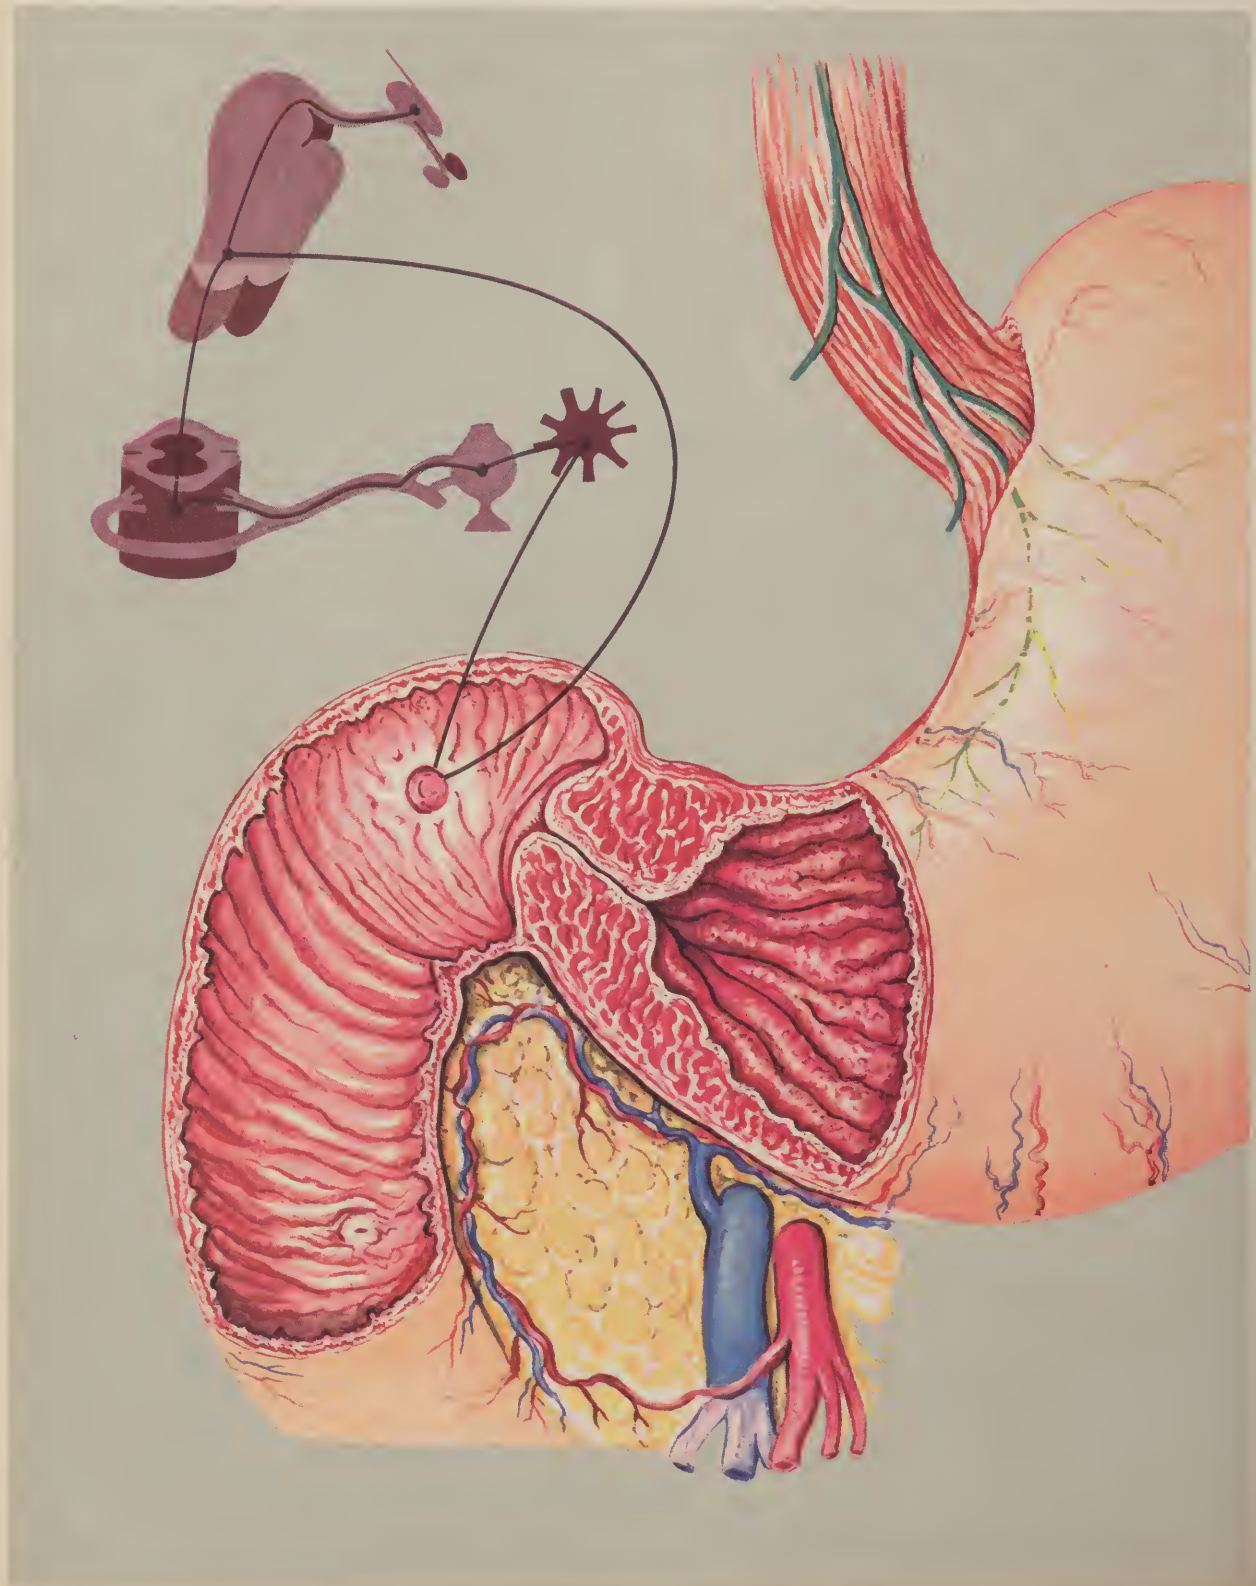
The fact is, NTz is more than a simple vasoconstrictor. It contains:

Neo-Synephrine® HCl 0.5%, a decongestant of unexcelled efficacy (in full adult strength) to shrink nasal membranes and allow comfortable breathing.

Thenfadil® HCl 0.1%, a topical antihistamine to help relieve itching and rhinorrhea.

Zephiran® Cl 1:5000, an excellent wetting agent and antiseptic preservative to aid rapid spread of components.

NTz, for temporary relief of nasal symptoms, is well tolerated, but overdosage should be avoided.



Available: NTz Nasal Spray in squeeze bottles of 20 ml.; NTz Solution in bottles of 1 oz. with dropper.

Winthrop

Winthrop Laboratories, New York, N.Y. 10016

(1286M)

Healing the ulcer crater

Pro-Banthīne®

brand of

propantheline bromide

blocks ulcerogenic autonomic impulses

Therapeutic Activity—Pro-Banthīne blocks ulcerogenic impulses at both parasympathetic effector sites and ganglia and at sympathetic ganglia.

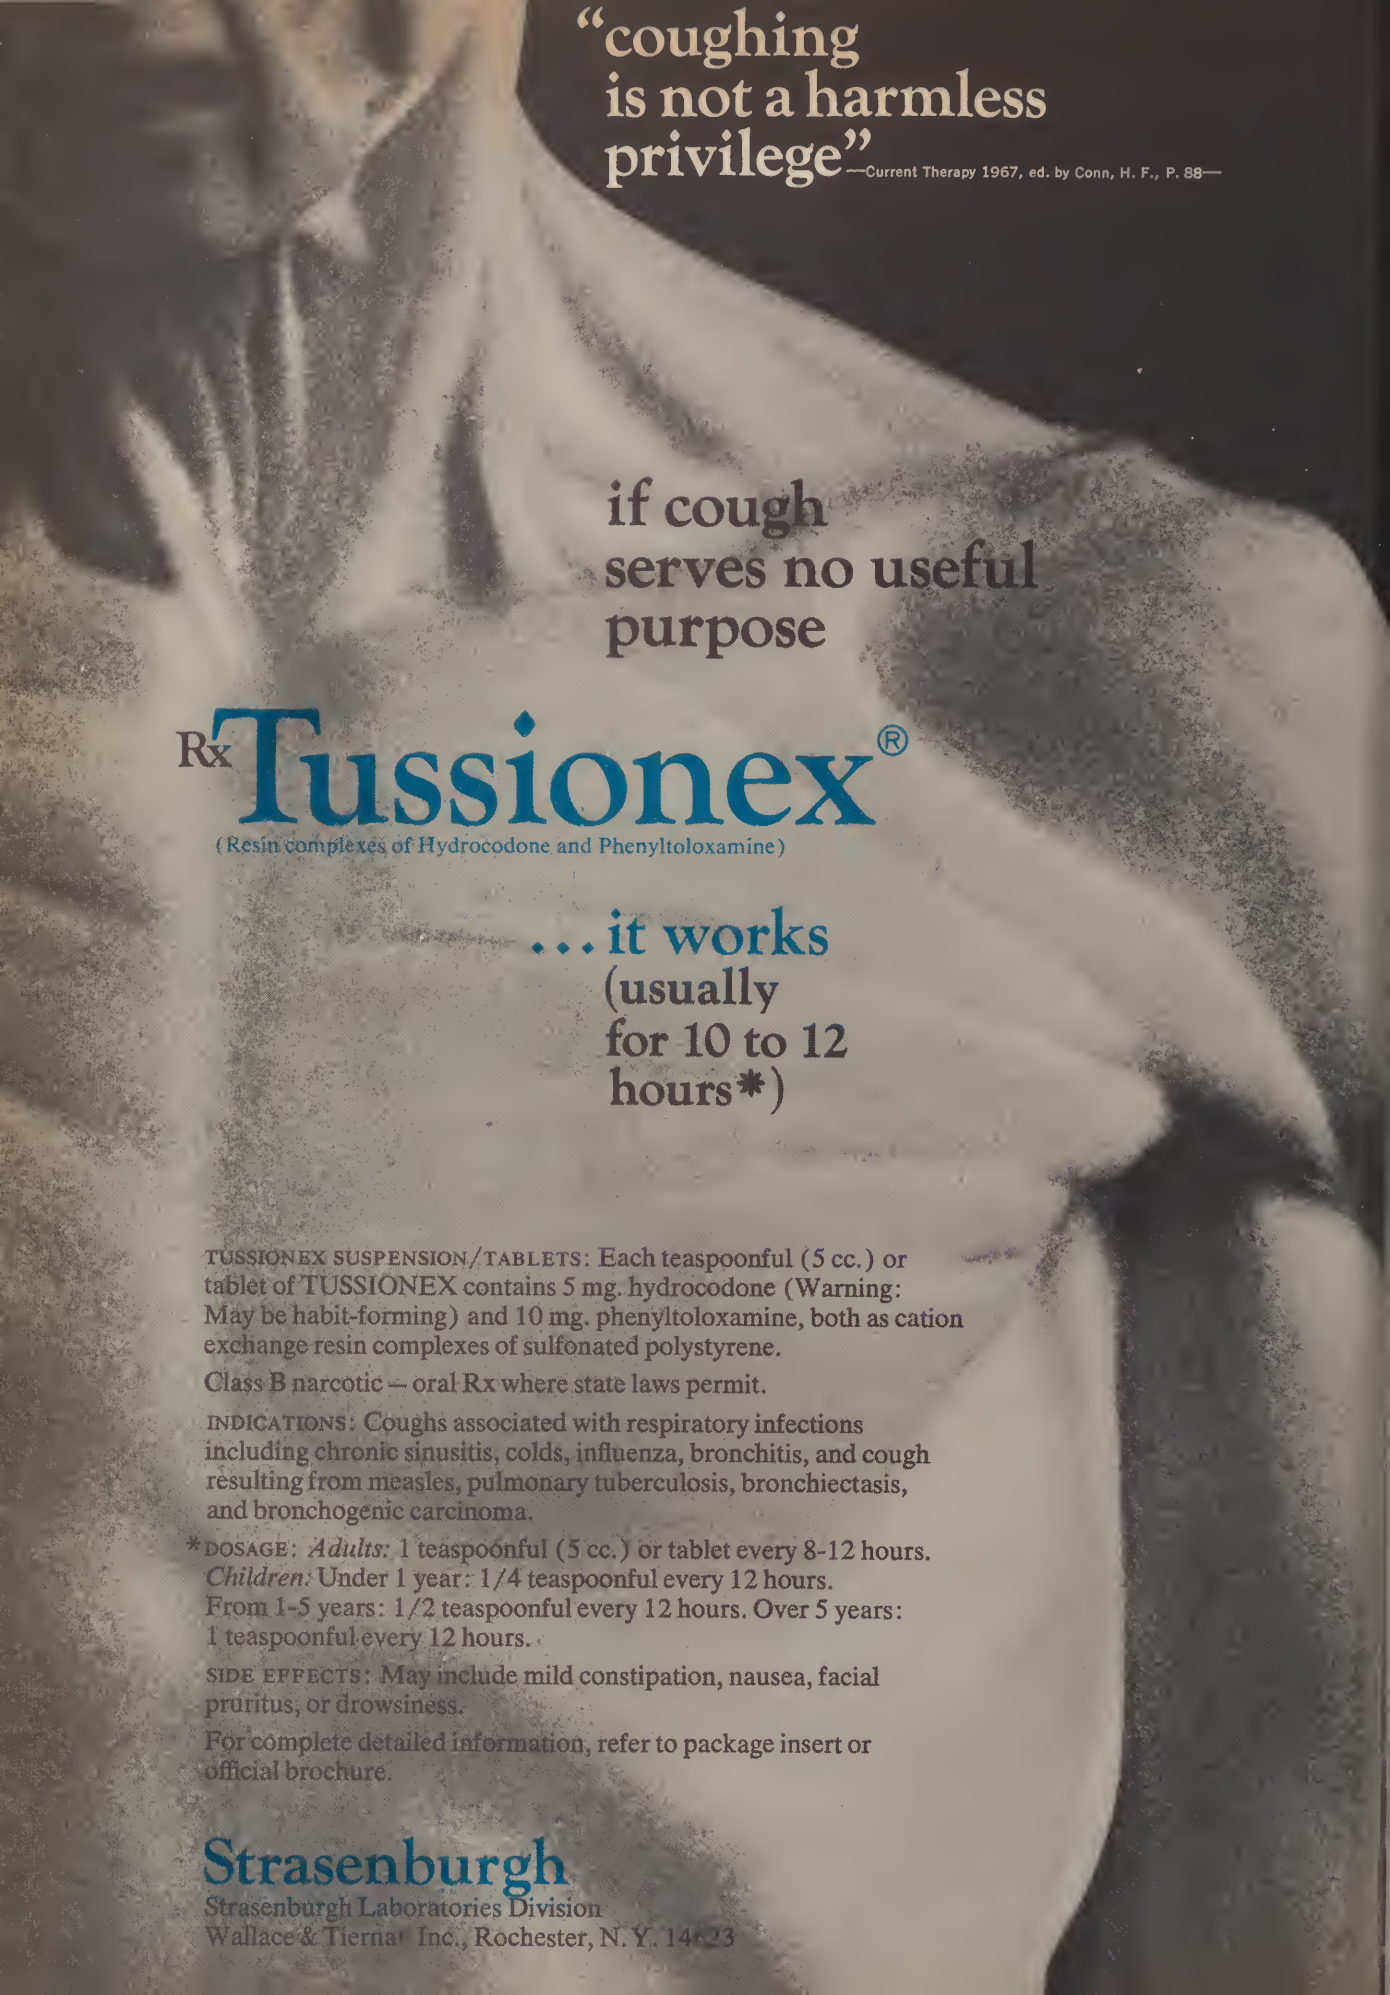
This dual action, a capacity quite beyond that of belladonna derivatives, has been shown repeatedly to reduce gastric secretion, to suppress gastrointestinal motility and to relieve ulcer pain.

Healing Environment—Thus, Pro-Banthīne, together with other standard measures, creates a favorable environment to hasten healing of the ulcer.

So widely is this ability recognized that for years Pro-Banthīne has been the most widely prescribed medication for treating peptic ulcer.

Indications: Peptic ulcer, gastroenteritis, pylorospasm, biliary dyskinesia, functional hypermotility and irritable colon.

Contraindications: Glaucoma, severe cardiac disease.



Precautions: Since varying degrees of urinary hesitancy may occur in elderly men with prostatic hypertrophy, this should be watched for in such patients until they have gained some experience with the drug. Although never reported, theoretically a curare-like action may occur with possible loss of voluntary muscle control. Such patients should receive prompt and continuing artificial respiration until the drug effect has been exhausted.

Side Effects: The more common side effects, in order of incidence, are xerostomia, mydriasis, hesitancy of urination and gastric fullness.

Dosage: The maximal tolerated dosage is usually the most effective. For most adult patients this will be four to six 15-mg. tablets daily in divided doses. In severe conditions as many as two tablets four to six times daily may be required. Pro-Banthīne (brand of propantheline bromide) is supplied as tablets of 15 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg. The parenteral dose should be adjusted to the patient's requirement and may be up to 30 mg. or more every six hours, intramuscularly or intravenously.

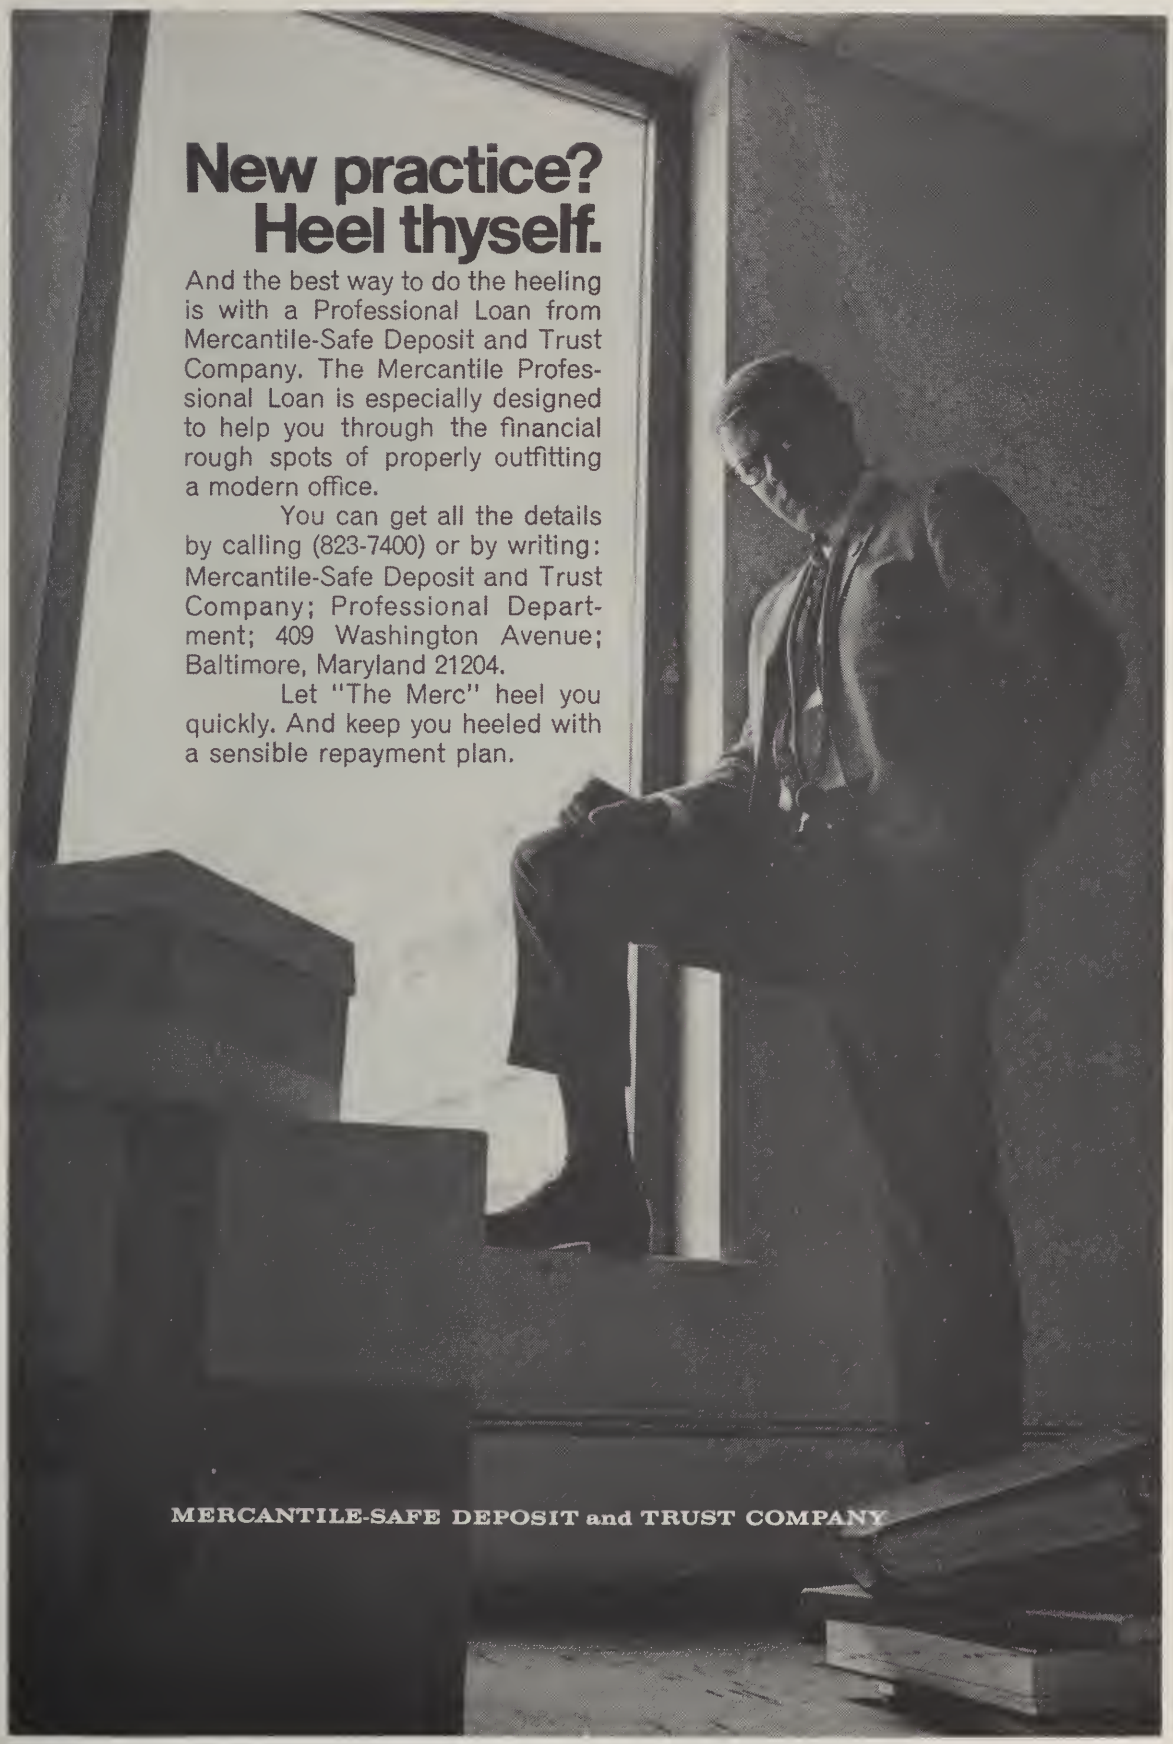
(Resin complexes of Hydrocodone and Phenyltoloxamine)

... it works (usually for 10 to 12 hours*)

TUSSIONEX SUSPENSION/TABLETS: Each teaspoonful (5 cc.) or tablet of TUSSIONEX contains 5 mg. hydrocodone (Warning: May be habit-forming) and 10 mg. phenyltoloxamine, both as cation exchange resin complexes of sulfonated polystyrene.

Class B narcotic — oral Rx where state laws permit.

INDICATIONS: Coughs associated with respiratory infections including chronic sinusitis, colds, influenza, bronchitis, and cough resulting from measles, pulmonary tuberculosis, bronchiectasis, and bronchogenic carcinoma.



*DOSAGE: *Adults:* 1 teaspoonful (5 cc.) or tablet every 8-12 hours. *Children:* Under 1 year: 1/4 teaspoonful every 12 hours. From 1-5 years: 1/2 teaspoonful every 12 hours. Over 5 years: 1 teaspoonful every 12 hours.

SIDE EFFECTS: May include mild constipation, nausea, facial pruritus, or drowsiness.

For complete detailed information, refer to package insert or official brochure.

New practice?
Heel thyself.
And the best way to do the heeling is with a Professional Loan from Mercantile-Safe Deposit and Trust Company. The Mercantile Professional Loan is especially designed to help you through the financial rough spots of properly outfitting a modern office.
You can get all the details by calling (823-7400) or by writing: Mercantile-Safe Deposit and Trust Company; Professional Department; 409 Washington Avenue; Baltimore, Maryland 21204.
Let "The Merc" heel you quickly. And keep you heeled with a sensible repayment plan.
MERCANTILE-SAFE DEPOSIT and TRUST COMPANY

"I feel
so light-
headed..."

She's confused...and frightened. Yesterday, her complaint was a brief spell of dizziness. Next week, she may be troubled by prolonged nausea or tinnitus. The symptom of vertigo is a constant problem in geriatrics, and regardless of origin, duration, and frequency, such episodes can result in severe emotional and physical discomfort for the aging patient.

You can help prevent such problems with

BONINE®

(MECLIZINE HCl)

protects most patients against nausea and vertigo up to 24 hours with a single dose.

Whether the symptoms are due to Ménière's syndrome, labyrinthitis, vestibular dysfunction, or cerebral arteriosclerosis, most patients with nausea and vertigo respond remarkably well to Bonine (meclizine HCl). A single dose usually protects up to 24 hours. In difficult cases multiple daily doses may be necessary for maximum response.

One-a-day dosage costs your patients less. And fruit-flavored Bonine chewable tablets are more convenient to take anytime, anywhere—without water. Side effects are infrequent and mild, even with prolonged use.

Precautions: Although the incidence of drowsiness and atropine-like side effects such as dry mouth and blurring of vision is low, the physician should alert the patient to the need for due precautions when engaging in activities where alertness is mandatory. *Use in women of childbearing age:* In weighing potential benefits vs. risk in women of childbearing age, consider the fact that a review of available animal data reveals that meclizine exerts a teratogenic response in the rat. In one study a dose of 50 mg./kg./day (50 times the maximum recommended human dose) produced cleft palate in 2 of 87 fetuses when administered to the rat at critical times during the first 15 days of gestation. At doses of 125 mg./kg./day, meclizine will produce 100% incidence of cleft palate in the rat. At doses of 25 mg./kg./day, decreased calcification of the vertebrae and relative shortening of the limbs were also produced in the rat, but experts disagree as to whether this is a teratogenic response. While available clinical data are inconclusive, scientific experts are of the opinion that this drug may possess a potential for adverse effects on the human fetus. Consequently, consideration should be given to initial use of a nonphenothiazine agent that is not suspected of having a teratogenic potential. In any case, the dosage and duration of treatment should be kept to a minimum.

Supply: 25 mg. scored tablets.

The Age of

"Harmony and understanding,
Brotherhood and trust abounding . . .
This is the Age of Aquarius . . ." —Hair

The production of "Hair" has revived an astrological fact, which has been in operation since 1904. To many, the Age of Aquarius may sound like a superstitious bunch of bunk. But to many others—the younger generation specifically—its power of suggestion is strong enough to transform starry predictions on a page to the really real. It's not just enough to know what age we're in; and rather than make the astrologers look like bloomin' fools—which they have appeared to be to all nomenclators, with the exception of ardent housewives, we'd rather make ourselves look like gods. ("I believe in God and God believes in Claude—that's me.") This isn't so hard to do if you take a walk in space by launching an LSD cloud or levitate to a cinemascope vision in a Yoga meditation. But to the ones who are just beginning, and to the ones who are left over from the nondescript generation, it's downright exasperating. It is especially frustrating to those who have chosen to walk the quietly militant road of freedom only to discover that the world cannot be remolded as easily as an aquarian pours water over a barren earth.

Aquarius

Nevertheless, instead of folding their napkin and
leaving the table—which is what they claim
the previous generation did—they promise a roar so
deafening, and so compelling that the world will
break into crescendoes of love and brother-
hood and, at last, peace.
So when names are recorded in the stars, these
are the persevering ones who will shine the
brightest—not the observers who find the water too
turbulent for their tepid natures, and who still
persist in living in the twilight zone, nor
the ones who dismiss the world with a wave
of the hand on their way to outer euphoria.
In the end, the history books may revert to
astrology books to define this Age of Aquarius, and
in doing so we hope they don't miss the
bold print: "The stars impel, they do not compel!
What you make of your life is largely up to you."

the 20th Century adolescents

The Adolescent Patient:

An Overview

SHELDON D. GLASS, MD
Co-Director, Family and Youth Center
Dept. of Psychiatry and Behavioral Sciences
The Johns Hopkins University School of Medicine

The papers presented on the following pages are from the symposium on the 20th Century Adolescent, held November 13, 1968 at the Eastwind in Baltimore. The symposium was sponsored by Geigy Pharmaceuticals and the Medical and Chirurgical Faculty.

The 20th Century Adolescent is a topic which in recent years has stirred the interest and demanded the attention of the entire nation. We have had overt rebellion from our adolescents. They are demanding IN. They want "a piece of the action."

Adolescence has been defined in many ways. The definition that I like best is the one which states that adolescence is the time when your son stops asking you where he came from and starts telling you where to go.

Biologically, adolescence can be considered to begin with the first evidence of physical sexual maturation and end with the complete development of primary and secondary characteristics. Psychologically, adolescence may be different in various individuals from diverse cultures. Young adults who are chronologically and physically adults may be psychologically adolescents. Comparative studies of different cultures have shown that environmental factors do influence the reaction of the adolescent and his psychological development. This is important to note in therapy. Man is an adaptive animal and will respond to his environment.

Although internal stimuli, such as the increase in aggressive and sexual drives during adolescence, are important factors, environmental factors are equally significant. In some instances, they may be more important in influencing the psychological development of the individual and in affecting his ability to handle these internal factors.

Because many changes occur in the adolescent, both internally and externally, he is more anxious. This is reflective of the changes within himself, and his interaction with the environment. For this reason—and this is where I perhaps differ from some of my colleagues—I insist that all the members of the family, or at least the parents and the patient, be present for an opportunity to communicate with each other. Sometimes, the family or the parents of the individual patient may not be ready for this in the initial phases of treatment. However, I program it so that both the patient and the family know that this will eventually come about when I think it is technically in the best interest of the treatment plan. (This has been called conjoint family therapy.)

When the adolescent is still in high school and living at home, I insist upon this treatment program, with some exceptions of course. If the patient has moved on to college or is not living at home, then I may or may not work with the family, depending upon the technical advantages and disadvantages to both the patient and the parents. If we don't consider interaction with the family, I think we place the patient at a disadvantage. In a structured setting, such as the physician's office, the patient can identify with the physician and gain confidence in his development of independence. In addition, the parents can gain on-the-spot insight into the way they relate to their youngster, and have an opportunity to reflect on their own ideas.

More and more, the generation gap is being brought to my attention. The other day a youngster, who was working through an identity problem by lifting weights, came in. I noticed he was starting to develop muscularly. I said to him "You're beginning to look like Charles Atlas." And he looked at me and replied, "Who's Charles Atlas?"

Another situation occurred a few days ago in a seminar that I was involved in—and I thought this was very fascinating. A boy was referred because he was expelled from school for smoking on the school grounds. When the person who was presenting the case history paused, five people immediately reacted by saying, "What was he smoking cigarettes or marijuana?"

During development the adolescent is concerned with many things. I am going to take the liberty of grouping them into three main categories, although each is not a separate entity.

The first is body image. The adolescent has significant growth spurts. His body is changing, he gets gawky at times. He has a tremendous appetite, and he occasionally gets acne. This influences the adolescent considerably; he becomes self-conscious.

We had a youngster who was referred to a group counseling program in one of our schools because he wasn't participating within the classroom. It was only until the second session, when he did start to participate, that we recognized the reason for his isolation in the classroom. He was constantly keeping his hand over his mouth because his two front teeth were missing. This was the primary reason for his non-participation in the class.

The second consideration is that of identity: Who am I? One youngster who I had been treating about a year ago came in one day and said, "You know I was working with my mother in the kitchen. We were both doing dishes, and I suddenly recognized that I was who I was and she was who she was and that we were different people." This is significant to the youngster. He is trying to determine his own identity.

Identity itself can be divided into two parts. One is the concept of oneself as an individual, and the other is the concept of oneself as a member of the group. Although these identities are closely related and transact with one another, they are different.[2]

Group identity is important during adolescence. If you have a youngster who isn't socializing and doesn't have peer relationships, then you ought to review the situation closely. One of the most significant examples of this phenomenon is seen in the inner city schools. On individual examinations the youngsters may have significant self-esteem and self-worth. They are healthy, strong boys and girls, but they are not performing in the class. One of the reasons for this is that they adapt to the environment of the class, which may be one of non-learning. In order to survive, they have to conform to the group. As a result, their conformity interferes with the educational process that the school is trying to promote.

On the perimeter of the city this also can be a problem. Youngsters may be in groups in which everyone is going to a "big league" college, such as Harvard, Yale, Cornell, Hopkins, Radcliffe, and Wellesley. When a youngster can't quite make that league, then he may be in trouble, because he may feel he can't identify with his peers.

This is also important in families. (The family

is the primary group.) Everyone in the family assumes a role as part of the family unit. While the youngsters are developing their independence, they must decide what their role is and has been in the family, and then decide what their role is or can be outside the family.

Gradually the adolescent should be given the opportunity to develop from a dependent position in early adolescence to an independent one. However, when he does, it creates some of the difficulty that we often observe within the adolescent youngster. As his mood fluctuates, he assumes a very independent position, telling his parents he's going to do it "this way," to the point that his parents are almost ready to kick him out of the house. Then he says, "Well, I'm not ready to be that independent", and he becomes exceptionally nice. Then, of course, he gets too close. He can't tolerate this, so he swings to the opposite extreme again. This explains in part, though not totally, the mood vacillations in adolescence. It is during periods such as these, that bringing the entire family together to orient them to the change of the adolescent, as well as themselves, is particularly helpful. Sometimes we spend so much time with the individual adolescent that we forget that he has parents, who are also going through a change.

The most difficult change for the parent is one of separation from his youngster as the youngster becomes more independent. This means that not only the role of the youngster is changing, but also the role of the parents in relation to that youngster. Sometimes this is not as easy for the parents as we may believe. The question of dependency, of not wanting to let go, is one on which the parents must reflect. The fact that they also are reliving their own adolescent experiences may influence their attitude and their reflections on their own children. This, in turn, may be complicated by the appearance of the Oedipal problem. Since the daughters and sons are becoming more attractive, both adolescents and their parents are becoming more sensitive and aware of each other.

During the period of adolescence, there is a revolt against parental authority. It is important that the parents set limits. This, I believe, is a group dynamic. The youngster will know where he can go and where he can't and where he can draw his battle lines for independence. It gives structure within the primary family group, which is essential, so that everybody can adapt and readapt accordingly.

I had one youngster who was referred to me because he became a high school dropout. I asked him why he became a dropout. He said, "Well, the first thing I did was I grew long hair, and nobody paid any attention. The next thing I did was that I wore dungarees, and nobody paid any attention. The next thing I did was I started to do poorly in my grades, and nobody paid any attention. But when I dropped out of school, that's when they started paying attention."

Because the youngsters are trying to become independent, they do need parents to interact and to conflict with. It's better to draw the battle lines along things like long hair and clothes, than schooling.

Another consideration would be the expectancy effect. Sometimes parents expect their youngsters to do certain things and, in fact, the youngsters do attempt to fulfill the fantasies, and wishes of the parents. I think this is important to consider.

Are the kids of today different from the kids of yesteryear? I'd say, yes, they have to be, if we are adaptive social animals. In the last twenty-five years we've had three wars, which have affected every family, either directly or indirectly. We now can have charter flights to the moon for Christmas, and this is an important consideration in time and space. We have weapons that can annihilate mankind, which have to affect the entire community. These factors influence all of us, not just the adolescent.

But I think that one of the primary considerations now facing our adolescents can be called the "opportunity gap." Technological advances have outdistanced our current social models. Parents ask me, "What can I do? There are no jobs available for the kids. What is there to do at home? We have automatic everything." This is the challenge. We have to redesign our socialization concepts to give our youngsters an opportunity to participate. They want in. They want to communicate with people, their parents and their friends. They want an opportunity to do something worthwhile. They want to be able to tackle new jobs. The kids of today are sophisticated and they're smart. Like any adolescent of most generations, they have tremendous enthusiasm and energy; like any adolescent they are willing to get involved.

We have to redesign our institutions, such as, our public schools, our colleges, our universities, and our community programs. This must be done on a local and state basis so that the youngsters can get involved in organized

activity enabling them to test themselves, to expand their ideas, and to develop their creative ability in ways that perhaps we haven't conceived of before. Until we are able to do this, we are going to have adjustment problems in adolescents, and we're going to be seeing more and more adolescents as patients.

Good medicine is also prophylactic medicine. We should be able to talk with and treat the adolescent, but we should also participate in our community activities. In this way we can help bring about the changes, which are so necessary, to allow our youngsters to participate in the community in a meaningful way. Part of this redesign has to be and should be done by the adolescents themselves. Nevertheless, when we can invite them to participate with us to design programs for them we will be beginning to bridge the opportunity gap that currently exists for our adolescents in the 20th century.

Implications of the Sex Revolution in the Adolescent's Search for Sexual Identity

JAMES F. MASTERSON, JR., MD
Associate Professor of Clinical Psychiatry
Cornell University Medical Center;
Attending Psychiatrist
Payne Whitney Clinic
New York, New York

Perhaps the main implication of the sexual revolution is the fact that the topic is mentioned almost always in the course of everyday conversation. It has been taken out of the bedroom and into the living room. There are a number of reasons for this, I think. Everyone has, or had, sexual conflicts in his development which he resolved to, perhaps, a relative degree. Still, he wants to know more about them. As a result, he goes to hear talks or read articles about the sexual revolution, since he feels he is involved in it too.

Now, we are not just living in a time of sexual revolution, but also in a time of social revolution that is just as vast, as profound, and as sweeping as anything since the period of the Renaissance. It involves a complete restructuring of the relationship of the individual to authority which places much greater stress on the needs and rights of the individual, and the necessity of the various figures of authority to rely more on reason and flexibility, rather than on rules and discipline in their dealings with the individual.

This begins obviously in the home, in the relationship between parents and children. It's followed through in the schools in the relationship between the school and the student; and in the society as a whole in the relationship between the citizen and the laws and the courts, the employer and employee; and in religion between the hierarchy and the laity. People are demanding not only that they be given adequate consideration, but that they also participate with the authority in the decisions involving their own destiny. There are numerous examples of this every day in our newspapers. Even in my own home it filters down. My 11-year-old son is a good example. He was leaning over the bed one day and I gave him a boot on the backside, sending him sprawling over the bed. And he turned around and said, "Parental brutality, an invasion of my rights."

You also hear a great deal about students rioting because they want more voice in the government of their schools. Also, in medical schools today the students are joining with the faculty in planning curriculum. And coming from New York City as I do, I don't have to look very far for examples of conflicts between employer and employee. We have them everywhere: policemen, firemen, sanitary engineers, teachers. As far as the law is concerned, I guess everyone is familiar with the Supreme Court decisions elaborating on the legal rights of suspects in the court. In religion too, there is enormous turmoil in the Catholic Church. So in essence, authoritarianism as we've known it through the years is out, and humanism is in. I think this augers very well for future generations in that it represents a dismantling of the remaining fragments of medieval thinking in the minds of men, and promises a future race that is more reasonably oriented and, hopefully, more responsive to human needs.

It's not surprising, then, that as part of this over-all social revolution we have something of a sexual revolution. Mankind is undergoing another dramatic swing of the pendulum in its effort to integrate harmoniously its sexual impulses and its social values. The evidence for this is also everywhere. The newspapers report that students are insisting that sex is a private matter and demanding the right to entertain girls in their rooms. A few months ago, the *New York Times* reported that the Columbia authorities turned this decision over to the student council, who decided there would be no rule at all about entertaining girls in their rooms.

Presently, the pill is much more widely used. The divorce rate is rising, and the percentage of those who have not had sexual intercourse before marriage is falling. The ancient fears of disapproval, of disease, of death, and of damnation are losing their former sway.

Now are these changes only in attitude, or are they also manifested in behavior? Are they the views and actions of a prophetic minority, of a fools' group, or the wave of the future? Is this revolution or evolution? Will it lead to a decline of social morality, or to greater human happiness? Is it only among the young, or does the older generation participate also? And why is it happening now? I am going to present a few thoughts on these questions, and also on some of the implications of these changes for the adolescent's struggle to develop his own sexual identity.

Many of the elders, I mean those over 40, view changes from the perspective of their own development, which is one based, for the most part, on Judaic-Christian ethics. Those with strict concepts of sexual morality have tended to see these changes as a sexual revolution and to ascribe them mostly to youth. It seems to me that they may err on both counts; for not only is this ferment taking place among adults, but also what we call revolution—meaning the overthrow of an established system of morals—the younger generation may view as evolution—the process of growth and development toward a new system of morals.

Let's look first at the adult world for signs of change in law, religion, and medicine.

In religion, the Catholic Church, more responsible than any other single agency for the prevailing concepts of sexual morality that have guided western man for the last 2,000 years, is in a furor at the present time, with congregations walking out on bishops, and bishops disagreeing with the Pope.

Concerning the law, there's a great desire throughout the country to liberalize abortion laws.

A recent survey of psychiatrists indicated that 95% felt that the law should be more liberal. Efforts to achieve this end recently just barely failed in New York, but, as you probably know, did succeed in Colorado. Thus, the law's views on sex are being revised.

Medicine, too, is changing in regard to sex. For the first time in the history of mankind, the light of reason in the form of experimentl scientific study has been introduced into the superstition, mystery, and the darkness that has surrounded human sexuality by Masters and Johnson's unique and pioneering studies of human sexual behavior.

These changes in religion, in law, and in medicine cannot be attributed only to youth. Clearly, the older generation, those charged with preserving, protecting, and transmitting the values of our culture, are actively involved in modifying these very same values. Meanwhile, what is happening among younger people? While their elders, being under less immediate pressure from sexual feelings, cope with these issues in a sober and intellectual fashion, the younger people, under more urgent pressure, have tried to apply these new concepts to their own lives.

Authorities differ as to the extent of premarital intercourse among students, but there is a consensus that the double standard increasingly has been discarded. College girls more often seek sexual experience during the college years than their mothers did. And there is evidence of earlier biological maturation in adolescence and a widespread pattern of going steady and of more open and vocal discussion of sex.

How extensive is this change? Though I read much in the press about the increased sexual freedom of the younger generation, I see less of it in my office and I read less of it, even in my own professional publications. My guess is that the advance guard of the younger generation is indeed exhibiting a great deal more sexual freedom, but that the majority, while still holding to traditional patterns in their behavior even as their parents did, are at the same time submitting their concepts, previously taken for granted, to serious and searching scrutiny. In other words, there's more change in attitude than in behavior. This view was recently supported in a study by Halleck of Wisconsin who found in his survey of college girls that although 70% thought there was nothing wrong with premarital sexual intercourse, only 22% had actually engaged in it.

I think there is more actual change in behavior in an older group in their mid-twenties. The teen-agers are not showing much change in their behavior, but their attitude has changed dramatically. They are more realistic. They are more concrete. They are more searching in seeking for answers. It's for them a daily urgent matter. And as Dr. Glass indicated, there is an enormous gap between them and their parents on this issue. The parents are concerned mainly about future and responsibility. They are either unaware that this represents a daily problem for the adolescent, or they are denying the immediacy and the urgency of it.

To illustrate this, I'd like to tell you a little about a talk I gave. When I was asked to give this talk to 100 teen-agers, grades nine through twelve, I was kind of worried that they might distort it in reporting to their parents, that I might be run out of town on a rail. Nevertheless, I decided to give it.

There were three talks, each one accompanied by a film. The first film was on anatomy and physiology, the second on the emotional aspects of sex, and the third on the religious approach to sex. In order to reassure the parents, a session was held with them first at which they were shown the film on anatomy and physiology. The minister asked me to attend, which I did.

I knew very well that the parents weren't particularly concerned about the religious attitude toward sex. What they wanted to know was what I was going to say to the teen-agers. I told them that when parents talk about this subject, they always stress responsibility; when kids talk about it, they talk about fun. What I'm going to say is that somewhere the two have to come together.

As a preparation for the talk, the adolescents submitted questions that they wanted answered. These questions, compared to the parents' anxiety about the future, revealed the enormous gap between the two. They also illustrated this ever-recurring human dilemma about sex. Here are a few examples.

The first one was from a 12th-grade girl. She was taking a rather intellectual approach to the matter: "How do you tell your children about the birds and the bees? You see, my parents only asked me once if I was aware of sex. What could I say—yes? I just don't know how to explain such a complicated mixture of emotion to a child; but I suppose I won't have to worry. They'll probably teach it in school by that time."

And then the girl gets down to brass tacks and asks: "What is the surest method of contraception?"

The next question was surprisingly enough from another 12th-grader, a male, who must be somewhat on the immature side. It said: "Where do you start with a girl on a date?"

And another one, a 12th-grade male who obviously had some plans on his mind which were making him uneasy, said: "Is it really right to get a girl high just to have fun with her?"

And then we turn to a senior girl, who obviously differs with her boy friend: "If a boy says that I don't love him because I won't have intimate relations with him, could you explain that this isn't true (without bringing God into it)?"

The next girl, also a senior, revealed some anxiety about the strength of her sexual drive. She says: "Is there such a thing as oversexed in females? If so, what can you do about it? What can you do about having a feeling of 'wanting'?"

Another girl: "What's wrong with premarital sex? I need better reasons than I've heard so far. I've heard all the usual reasons. What about a girl who goes with a guy for about two years? You really like each other. You get along with other people so you don't limit yourself too much, but you still really like only him and he likes only you. You've even talked of marriage after you've finished college. How far can you go? What is wrong with premarital sex while you are juniors and seniors in college if your relationship has lasted that long, and if you don't want to marry until after college?"

Another girl approaches the subject intellectually: "How much of a part does sex play in a relationship with a boy? How much should it play with a boy you date steadily? With a boy you date occasionally?"

Now here's a girl who touches all the bases in her concern about sexual intercourse, its consequences for her, for the boy, for her parents: "Is it proper for a girl to go all the way with a boy if she's going steady with him at an age older than 16? What do parents think of the younger generation having premarital sex, especially of one of their own children? What is it that makes a boy become so emotional when he is having intercourse with a girl; what actually happens to the boy? Do girls have a problem of becoming too emotional during sexual intercourse with a boy? If so, how can she prevent this? If a boy starts to become too involved in sex (during the lovemaking) how can a girl make him stop, yet still remain on friendly terms as before without sex? What happens when a girl loses her virginity? At the time she actually loses it, can a boy tell?"

The next is from an 11th-grade boy who seems to be a very compliant fellow. He says: "If a girl likes sex a lot, should I give it to her?"

Here are two tenth-grade girls who are rather indignant over the whole affair: "How can something so natural be so highly restricted? The purpose we serve is to reproduce the human species. Why then, psychologically, do humans feel the need to build up this tremendous ritual?"

The last question is from a ninth-grade boy: "As silly as it seems, I would like to know if there is a special time that intercourse should be done. Obviously, when a girl has her period, but what time of day or night should it be done?"

Well, the questions illustrate what a tremendous, urgent, immediate, and practical problem it is.

Now the end of the story is that I gave the talk and I tried my best to answer the questions. And it was like dropping a stone into a bottomless well. To my knowledge not a single one of those 100 teen-agers said a word about it to their parents at all.

Now to pass on to where there is more change in behavior. It is seen in those in the mid-twenties who have passed their adolescent stage of sexual development and who have a more secure sense of sexual identity. Among them traditional sexual morality has given way to the following view: Sexual play is avoided if possible, unless the boy and girl really care about each other. If they do care, sexual play occurs as a preliminary to sexual intercourse, which itself is seen as important, but subordinate to a higher value, a close interpersonal relationship. They have replaced the ancient virtue of chastity with that of fidelity, meaning that a girl has no compunctions about having sexual intercourse with a boy with whom she is in love, but today would no more think of being promiscuous than her mother did 20 years ago—but for entirely different reasons.

A good example of this is seen in a college girl named Sally. She had not expected to engage in sexual relations in college. In her junior year, however, she met a boy who, she said, was interested in her interests and she in his. Eventually, they did have sexual intercourse. Here is her description of her feelings. "It got to the point

where it really got frustrating not doing it. We had been going out together seven or eight months and it seemed if you feel strongly about the other person and you really love him, I don't see anything wrong with it, because it is a complete relationship, as complete as for some people who are married. This is one action where you give everything you have to the other person. It would have been almost wrong to keep holding back something that I really wanted to give."

Certainly, some would be alarmed that this sort of change may lead to a decline in morality. However, this change does not seem to encourage orgies or lack of control, but rather a different kind of control, self-control, based not on guilt or fear of disapproval, but on a concept of human relations that emphasizes self-respect, human worth, and dignity. But what are the reasons for this change?

The prevailing standard of sexual morality originated 2,000 years ago under the aegis of the Roman Catholic Church, and this standard emphasized chastity, virginity, and the spiritual merit of denying the flesh. It is these very standards that are being challenged today. Is it not possible that these standards which have held sway for so many years may at the same time contain some inherent handicaps to human expression which the younger generation is no longer willing to accept? Therefore, may they not view their efforts to emancipate themselves from their heritage as evolutionary rather than revolutionary? The fact that the impact of religion has decreased and science has increased would support this theory that their efforts are revolutionary. The impact of religion has decreased and science has increased suggesting that the use of reason, rather than religion, has become the guide for the conduct of one's life.

Another reason for the change in sexual views has been the persuasive influence, I think, of the psychoanalytical view. It sees the failure to integrate sexual impulses and feelings into the personality in a healthy way as impairing to personality growth and producing emotional difficulties.

Finally, the demands of women have become increasingly strong for equality on all levels. They see the double standard as keeping them from enjoying the pleasures of lovemaking, which men enjoy without serious condemnation. This rebellion is not in the direction of curbing men, but rather toward releasing women. Further, development of the pill which has freed womankind from its ancient servitude to pregnancy, together with the efficacy of penicillin, which has minimized the danger of infection, have removed two common sources of both sexual anxiety and control; thereby allowing women more freedom.

You might well ask at this point what does all this have to do with an adolescent's sexual problems. His older brother and sister are carrying out the revolution, but he is the one who must come to grips with its effects. He must develop his sexual identity through interaction with his fellows in the sexual mores of his culture. Therefore, it is he who is confronted with the shifting sands of a changing sexual morality in the social sphere at a time in his life when, lacking a personal sense of sexual identity, he must wade through those shifting sands in order to find that identity. Although the changing social climate immeasurably complicates his development since it gives him few certainties upon which to rest, at the same time it may afford him the greater potential by giving him more freedom to explore to find that identity.

Now what are some of the implications of this revolution? Let us consider the advantages first, and then the hazards.

There are many adolescents who, excessively inhibited, come to a dangerously late period of their development before fully realizing they have sexual problems. The revolution may impel these to recognize and seek help for their problems earlier.

For example, I saw a 22-year-old girl, Jean, who was a senior at one of the better eastern girls' colleges. She sat in my office and hesitantly and tearfully told the following story.

She had always been popular with boys and she began dating at 14. Initially, she had reveled in her successes—proof of her femininity. When she first became involved with a boy at 16, she developed such severe anxiety, nausea, and vomiting on each date that her only recourse was to end the relationship. She allayed her fears with the thought that she would grow out of this difficulty, but time was to prove her wrong. The pattern was already set and it continued unabated through the next six years. She feels she must have dated at least a hundred boys in college, but every time one became close, the symptoms would resume and she would have to break it off. She had to settle for an endless line of superficial dating

because she didn't dare get into a close relationship with a boy.

I could not help wondering as I listened to this attractive but immature girl, that more pressure of the kind implied by the sexual revolution might have brought help for her sooner.

An 18-year-old college sophomore is another example. She had been having emotional difficulties since the onset of puberty when she became anxious, depressed, withdrew from her friends, and spent all of her time on schoolwork. It was necessary for her parents to send her away to a special school for treatment. Gradually, she improved and went on to finish high school and to enter college. She again became anxious and depressed and came to my office for treatment. Although she maintained an active social life with an average amount of dating, she had never had a close relationship with a boy or any sexual activity, neither of which was a source of concern to her. After a year of intensive treatments and much working through of her anxiety and depression, it became clear that she was terrified of her sexual feelings and impulses so that she avoided any occasion with boys that might provoke them. She had always been dimly aware that something was wrong with her, and without facing up to the fact, anticipated that she would grow up to be an old maid.

The summer of her freshman year, she took a cross-country trip with some girl friends and was amazed to find, when visiting a number of campuses throughout the midwest, that girls her age—see it only happens in the midwest—were living with boys. This confrontation with changing sexual standards brought home to her, in a profound way, her own sexual immaturity and motivated her to work on her sexual difficulties and treatment. Twenty years ago this girl's sexual difficulty might well have escaped notice, perhaps even to marriage.

On the other hand, certain risks may accompany this sexual revolution. It may precipitate a premature attempt at sexual relations, either by those who are immature and not ready for it, or by those who are over-inhibited and cannot accept the emotional consequences of their actions. Their efforts then become abortive, and can have disastrous consequences to their emotional life as suggested by the following example.

I saw an 18-year-old freshman in college who had come from a well-to-do Puerto Rican family. He was raised as a strict Catholic and attended private Catholic schools. His father, feeling that further religious guidance was necessary, encouraged him to attend an Ivy League school. Here, he was exposed for the first time to differing views about sexual behavior, and when he fell in love with a girl from another college they would rendezvous in New York city in a hotel bedroom, and they would spend the afternoon lying in bed necking. Driven by his impulses but unable to consummate them because of his conscience, he developed intolerable sexual tension which he later relieved by masturbation which, in turn, led to depression and feelings of inadequacy. In these depressions he would roam the streets of New York all night seeking solace. Overwhelmed by these feelings, he finally was unable to do his school work, so he dropped out of college, and was referred to me for treatment. It took many months for him to understand the conflict between his sexual impulses and his standards.

In conclusion, there are a few things we should remember about the management of sexual problems. Too often, we abandon our youngsters at this critical time of life to work out their problems by themselves. We afford them no easy channels of communication to check their thoughts and impulses without being criticized or reprimanded. I suspect we do this because, often as not, the emergence of their sexuality recalls to us the sexual problems that we encountered at that time of life and have spent a good many years trying to repress.

Instead, we adults should neither lecture nor admonish, but rather help our charges to understand the human complexities of sexual life. We should discuss directly and openly both the developmental and the social issues raised by their behavior. In all candor, we might suggest that sexual life has to be subordinated to the total well-being of the personality, as well as to human relationships, and that it, therefore, entails responsibility as well as the pursuit of pleasure. Indeed, the greatest pleasure can be found only when it is subordinated in this way.

And finally, perhaps we should keep in mind that the goal of our efforts should be to keep our patients' and our children's developmental pathway open to a healthy and mature adult sexual life, one that combines the utmost in pleasure with the necessary amount of responsibility, first to their own conscience, and then to their fellow human beings.

Addiction, Psychodelic Experimentation and Abuse of Drugs by the Concerned Generation

DALE G. FRIEND, MD
Assistant Professor of Medicine
Harvard Medical School
Boston, Massachusetts

Drug addiction appeared very early in the development of the human race. Poppy seeds have been found near the dwellings of primitive man, and we know natural products capable of causing addiction in man have been in use for centuries. No new substances present in nature in this category have been found, in spite of the extensive search. Plant products capable of exerting psychological effects have also been in use for centuries. However, there have been discoveries of new substances of this type in recent times, and there is good reason to believe that additional agents will be found. In this category, the very nature of the action of these drugs makes it difficult to develop a true assessment of their action. It is easy to be misled as to the effect on the patient, if any, and the type or pattern of their action. For example, claims made by certain groups, that smoking dried banana pulp or peels gives a psychological effect, are without foundation. Such could either be a delusion resulting from a placebo effect, or a hoax put on the squares by the hippies.

Although man has experimented with drug effects for centuries, there appears to be a new and perhaps a more ominous pattern emerging in recent years. In primitive societies, and probably through most of known human existence, drug use was confined to the older, more experienced members of society. Frequently, they were used in tribal rites. Now, for the first time, we are seeing the use of various drugs in young, inexperienced adolescents. Alcohol, marijuana, LSD (lysergic acid diethylamide), various solvents, and other agents are now being used in high school and even in junior high school groups.

Consequently, there is a great deal of misinformation and confusion concerning drug abuse. For many years, the scientific world made a distinction between what was considered drug addiction and drug habituation. This type of distinction really has no place in modern thinking, since investigators and people with knowledge in the field know that addiction can be a matter of psychological dependence as well as physiological dependence and may take place with a variety of substances, even those which are not known to possess any high degree of addicting propensity. Habit-forming narcotic drugs such as heroin, morphine, opium, meperidine, and derivatives of these substances have been a source of trouble to various civilizations through the centuries. At times, large segments of certain societies have been infected with addiction to these agents as, for example, China in the early eighteenth century following the Opium Wars. For the most part, however, addiction to narcotic drugs has not been widespread in modern civilizations. It has always been a source of worry, but society has constantly fought well enough so that it has been restricted to a very limited percentage of the population. For instance, in the early part of this century in the U. S. A., there was thought to be one addict to opium, or its derivatives, in every 400 people. This was a result of the widespread sale of narcotic-containing patent medicines. After the Harrison Narcotic Act went into effect the rate fell to one in 4,000. Even so, there is good evidence to indicate that the number involved is again increasing at the present time, both here and in England.

The Three General Categories

Clinically, the physician can divide addicts into three general categories. First, there are the socio-economically deprived individuals who become addicted through ignorance and the bad influences around them, where they are subjected to companions who are involved in the addiction rackets, and carefully led into the addiction by pushers who make supplies available until they are hooked. Then they are no longer able to resist the effects of the drug, and become victims of the rackets that control the addicting drug market. Oftentimes, these individuals are not only socially and economically deprived, but they are individuals of races which have been discriminated against. Usually, they come from broken homes, and a great many of them have severe psychological conflicts created by their surroundings, their station in life. These factors, and various others, have operated to put them into a situation where they do not feel that they are in the main stream of life. They have deep resentments, severe mental suffering and a sense of hopelessness that makes them mentally receptive to the peculiar euphoric effect of narcotic drugs. In other words, it seems to these individuals that the solution to their suffering, both mental and sociological, is the relief afforded by the drug. They substitute an unreal world of drug euphoria for the real world which, in many cases, they feel has rejected them. It is precisely with this group with unsolved emotional and sociological problems that narcotic addiction has gained such footholds. It is these individuals that present serious problems in treatment.

A second group are those who become addicted through medical accident. These are individuals who have a stable position in society, and who have no need for any artificial substitution for emotional stresses. They become addicted because of the pharmacological effects of the drug. They are patients who have suffered some debilitating illness associated with considerable pain and have been given narcotic drugs for the relief of their pain. Some time after a period of two or three weeks, the patient becomes physiologically dependent on the drug because the initial cause of the pain, which may by now have ameliorated, is mistaken for the pain of addiction withdrawal. The patient and, oftentimes, the physician are not aware that this is taking place. It is only after a period of several weeks when there is no obvious pathological or physiological reason for the pain, that the physician realizes that the pain now is that of withdrawal. When this situation is recognized, and the patient and physician take proper measures to withdraw the patient, these individ-

uals almost always get well. However, they must be handled properly. They need firm guidance for a period of time until the damage done by the physiological dependence has been entirely eradicated.

Finally, there seems to be a third group of individuals who on the surface appear to have no real emotional or sociological conflicts, but who, as a result of experimentation or during temporary stress, take narcotic drugs until they develop a physiological dependence. They then use the drug to mask the difficulty of facing up to life's problems. Frequently, these individuals are most difficult to manage. They tend to return to addiction very much like the first group, although there is less overt reason for them to do so, since there are more factors working to benefit them than in the first group. All too often, patients in this category are likely to be intellectuals or professionals such as, physicians, nurses, and pharmacists.

Another useful way to classify narcotic addicts is to consider the psychological and emotional make-up of the individual. In the first division are those with inadequate personalities. These are the passive, dependent, demanding patients who expect society to take care of them. They are self-centered, immature, and cannot solve life's problems. These individuals use narcotics as a prescription for their anxiety and frustration.

Contrary to the first group are the hypomaniacs. They have high energy levels, causing physical overexertion, together with unrealistic aspirational goals. This leads to frustration and failure, since this type of person must continually win approval of others. As a result, he accelerates his activity until he is under serious pressure. Then he takes drugs to slow down and to relieve the pressure. Narcotics inhibit his self-critical faculty, and insulate him from reality.

This next group is also characterized by extreme self-criticism and depression. This attitude makes him fearful of mistakes, so that he underacts when frustrated. In seeking oblivion, drug addiction allows him to feel normal since he is less critical. However, use of drugs, in turn, makes him feel more helpless and can lead to overdose and death.

Finally, there is the cyclical addict who goes from one extreme to the other—from hypomania to hypodepression. Correspondingly, his mood fluctuates between aggression and dependency. Various drugs are used, depending on mood, from amphetamines to narcotics.

The Effects of Narcotics

Narcotic drugs will affect every living tissue. Individuals exposed to the effect of addicting drugs for periods of a few days to several weeks almost invariably develop a physiological dependence. Although the basis of this dependence has never been thoroughly explained, we do know it is not entirely psychological: Tissues grown in tissue culture and gradually exposed to the effect of narcotic drugs, ultimately incorporated some effect from the narcotic drug into their growth pattern, so that they died unless the drug was supplied. Thus, some fundamental change has taken place in the cells exposed to these agents. The cell has developed a disorder which demands that it receive the drug, or injury to the cell will occur. In light of what we know about the action of certain chemicals, which affect enzymatic activity and liver cell's microsomes, whereby they become more effective in metabolizing certain substrates, it is certainly within the realm of possibility that addicting drugs may in some way influence these processes. This, in turn, may be harmful to the cell itself, or cause it to form certain metabolites which affect the cell.

There is another interesting aspect of addiction to drugs, whether it be alcohol, barbiturates, or narcotics, which gives many of us cause for concern. It is now known that most drugs readily pass the placental barrier and reach the developing embryo in the uterus. This causes addiction in the fetus so that upon delivery, the infant, no longer receiving his supply of the narcotic, develops severe withdrawal symptoms. For a few days after birth, a very uncomfortable period occurs until the infant has been weaned from the narcotic he received from his mother's blood. Presumably, these children, once withdrawn, progress normally. Whether this is really the case is of concern since cells thus exposed to narcotic action may well have developed changes in their structure or function. In this case, when the cells are exposed to even small amounts of a narcotic, they may, because of their previous sensitization, become easily affected thereby leading the individual into addiction once again. This reasoning might be extended even further in the case of pregnant mothers who drink alcoholic beverages, take barbiturates and other drugs. Possibly, the use of such drugs may sensitize the developing brain cells in the embryo, so that after birth, there

is a period of restlessness. However, no one pays much attention to it, and passes off an inability to sleep, excessive crying, and other manifestations of a mild withdrawal syndrome as part of the normal pattern of any new-born infant. Consequently, when the child grows into young adulthood where he again meets the old sensitizing drug, whether it be alcohol, barbiturates, or narcotics, he immediately develops a craving for the drug which rapidly leads him into alcoholism, barbiturate or narcotic addiction. Those of us who have taken careful note of alcoholic patients find that some of the most severe cases we have seen are individuals whose mothers were also chronic imbibers of alcohol. A great deal more information should be obtained in this respect, since prevention of cell sensitization may be a very important aspect in preventing addiction to various types of drugs.

Methadone Management

The withdrawal of patients addicted to the narcotic drugs is not very complicated. With the weak products that are available on the market today, withdrawal is not often a very serious problem. For example, the street heroin used to contain 50% heroin, but now the average sample contains about 6%. There are probably two reasons for this: One is the powerful and effective drive by narcotic agents to prevent its entry into the country and their success in seizing huge amounts of it from time to time. The second reason is probably the greed of the racketeers who stretch it as far as they can to increase their profits. For those who have been exposed to large doses of narcotic drugs, the most satisfactory form of withdrawal is hospitalization, and a substitution of 1 mg methadone for each 4 mg of morphine or heroin, or 10 mg of meperidine. Over a period of about ten days this dosage is rapidly reduced. If the patient becomes restless, the use of chlordiazepoxide in large doses in the order of 50 or 100 mg or more daily, can be used to aid the recovery. Once the patient is completely off the narcotic drug, it is extremely important to set up a very careful rehabilitation program.

In general, if the socio-economic situation can be improved, it will have an important bearing on the recovery of the individual. There must be a careful follow-up with 24-hour supervision on the part of family, friends, or groups, for many months after the drug has been withdrawn. Usually, an interested husband or wife, brother or sister, is able to accomplish more than social workers, psychiatrists, or physicians. It must be remembered by everybody concerned that the patient is extremely vulnerable. He has no will power to reject the efforts of pushers. Even the slightest emotional disturbance will cause him to become restless and lead him rapidly back into addiction. Therefore, someone must "baby-sit" with the patient continually to prevent these sudden urges to return to the previous addiction. In recent years, several organizations have sprung up which tend to afford this type of supervision, and for the most part, they have been valuable in helping the dependent addict.

Presently, there is considerable interest in a program of substituting methadone in very large doses to control the addiction craving of the former narcotic addict. In the hands of very devoted interested workers, there seems to be a reasonable degree of success with this program. However, many feel that this is substituting a weak narcotic for a stronger one, and is really hindering a satisfactory cure of the individual. As noted by many observers, if the addict can learn to live with his addiction by never increasing his dosage to obtain euphoria and by taking just the amount he needs to prevent the severe pangs of withdrawal, he can live for years in this situation while carrying on a useful occupation, and, on the whole, being adjusted reasonably well to society. Therefore, many suspect that this is what is happening in the methadone program, and from past experiences it is known to be reasonably effective.

Undoubtedly, there is need for considerable improvement in the management of addicted individuals. Certainly, those in socio-economically deprived areas should be, if at all possible, removed from these areas, retrained, rehabilitated, and reestablished in useful, productive jobs in areas where contact with narcotics would be almost impossible.

Barbiturates, amphetamines, and meprobamates are also addicting drugs. Usually, dependence develops after these drugs have been abused severely. Large doses, in the order of four to six times the usual dosage, given over long periods of time, are usually the cause. Since withdrawal can be dangerous—leading to agitation or convulsions—the patient is locked to the drug until competent medical help can be given. Abuse of these drugs leads to serious deterioration—mentally and physically. Usually withdrawal can be accomplished without much distress by gradually reducing the dosage: Use of a tranquilizer such as chlordiazepoxide and

the anticonvulsant, diphenylhydantoin, is helpful. Complete cure is, at times, most difficult because of the underlying personality.

On the other hand, individuals can become addicted psychologically to alcohol, tobacco, propoxyphene and a host of other such things. Although addicts of this type can be withdrawn successfully, the initial reason for their drug abuse presents the greatest problem. In this regard, I am reminded of a parody on an ancient quote, "We have met the enemy and they are us." Likewise, the drug is withdrawn, the patient does not like what he sees. His emotional instability or psychological aberrations led to the drug abuse in the beginning. It is the real problem, and, unless it can be resolved, permanent cure is not likely. Nevertheless, with skillful guidance, effective persuasion, education, and development of a new interest and outlook, the majority of these individuals do succeed.

Hallucinogens

In contrast to the previous drugs are the hallucinogens. The principal ones at the present time are: LSD, and its derivatives such as, lysergic acid monoethylamide—the active principle of the seeds of the Mexican morning glory which is about 5% as potent as LSD—mescaline from the Mexican cactus, myristicene from nutmeg, psilocybin from the toxic mushroom of psilocybe mexicana and its active principle psylocin, dimethyltryptamine, marijuana and N,α-dimethylphene thylamine (methamphetamine), and more recently STP (2, 5-dimethoxy-4-methyl-amphetamine) specially processed petroleum (it makes your engine run better). These have been introduced as drugs which bring about severe hallucinogenic, mind-altering properties. Sniffers use many agents from highly volatile solvents such as the toluenes to even gasoline.

Drugs in this category have created an unusual amount of attention in recent years, and certainly have provoked much controversy. They are, at present, a serious problem, challenging both society and medical science. All of these drugs are capable of producing various degrees of hallucinogenic distress. Their use, like that of the narcotics arose in antiquity. It is said that the Vikings worked themselves into a war-like mood by munching on the poisonous mushroom, Amanita Muscaria, and these same mushrooms, as well as mescaline, were used in the religious ceremonies of the Aztecs. Even today, members of the Native American Church use mescaline in their rites. The use of marijuana as hashish is also ancient. It is said to have been a tool in the hands of the hashishins. This word meaning takers of hashish gave origin to the term assassin, signifying one who took hashish to induce ecstatic visions of paradise before he set out to face martyrdom while performing a treacherous murder.

The effect of LSD was discovered accidently by Alfred Hoffman, a Swiss chemist, in 1943, when he tasted some of it. The drug had been synthesized in 1938 by Stoll and Hoffman in the course of their work on ergot derivatives. It is the most potent of the hallucinogens. A dosage of 75 to 150 micrograms will give a hallucinogenic effect. Doses of 1.0 mg have been used with a serious disruption of mental processes. Conversely, mescaline is given in a dose of 200 to 400 mg to induce the usual effect. Psylocybin requires a dose on the order of 10-20 mg for proper action.

A comparatively recent source of central nervous system stimulants are the amphetamines. They were first synthesized in the 1930's by Alles, who was trying to make a cheaper substitute for 1-α (1-methylaminoethyl) benzyl alcohol (ephedrine). Methyl amphetamine was prepared by Japanese chemists and used by them as an antisoporific in World War II. Subsequently, many derivatives of amphetamine have been synthesized. Racemic amphetamine, its dextrorotary component, and methamphetamine are widely used in a variety of situations, many of which led to severe abuse, such as auto and truck drivers using them to stay awake to drive longer distances, housewives getting a lift while reducing, students using them to keep awake to study more, and now hippies, meth heads, and speed freaks. The latter may inject 50 to 100 times the usual dosage of methamphetamine.

Originally, hallucinogenic properties of the hemp were obtained by eating a small amount of hashish, whereas now, it is more popular to smoke the powder prepared from the tops and leaves of the female plant. This is three to four times more potent than taking it by mouth. The exact dose is not known, but ⅔ of a cigarette or 1 to 4 gm of dried powder will give hallucinations.

It must be remembered our present day situation concerning the use of hallucinogens is not unique. We need only to recall the ether parties of the early 19th century where young people would assemble to sniff ether and have a hilarious

time. Out of these parties, knowledge of ether effects grew which culminated in its introduction into medicine by William Morton in 1846. Likewise, nitrous oxide, first known as "laughing gas," was used in similar circumstances. Inhalation was widespread, and such outstanding scientists as Humphrey Davies experimented with it. It was he who, going under the influence of nitrous oxide, suddenly thought that he had the secret of the universe. He immediately asked for pencil and paper so he could write the most profound message. Upon awakening, he eagerly sought the paper only to find that he had written, "Gad, the stench is awful." It is highly probable that much of the so-called "mind stretching," so widely acclaimed by some users of hallucinogenic drugs will end up with just about as much relevance.

The hallucinogens, except for bufotensin and dimethyltryptamine are readily absorbed from the gastrointestinal tract. For example, LSD appears in the blood extensively bound to plasma proteins. It does not seem to have an affinity for any special site, and only low concentrations are found in the brain. Its psychological effects, depending on the dose, may persist from 6 to 12 hours. Mescaline, though, is found concentrated in the kidney, liver, and spleen, it is mainly excreted unchanged in the urine. Up to 90% of a given dose can be recovered. Similarly, a high concentration of psilocybin is found in the kidneys and liver, and there is no accumulation in the brain. These drugs generally affect the peripheral autonomic nervous system as well as the central nervous system. Reactions to hallucinogens simulate an overstimulation of the sympathetic portion of the autonomic nervous system: the pupils dilate, the heart rate increases, and there is a rise in systolic and diastolic arterial blood pressure. There may also be some increase in blood glucose level, and there is commonly an increase in spinal reflexes, such as, the knee jerk.

The psychic effects are most significant as far as the central nervous system and the mental functioning are concerned. There is distortion of sense perception: vision becomes altered; there are hallucinations; dream-like thoughts occur; dream images appear; and there is a depersonalization of the individual. The emotional reaction usually present, varies from a euphoric sense of well-being, great pleasure, and excitement to the opposite extreme of anxiety and depression, the mood changing frequently during the periods of intoxication. The kind of reaction is influenced considerably by the environment, the personality of the individual, and the dosage of the drug. As to the mechanism of action in the central nervous system, very little is known. It is thought that there might possibly be some effect on neuro transmitters such as, epinephrine, norepinephrine, serotonin, acetylcholine or even histamine.

Although these drugs have been in use for many centuries, there is still no real consensus of opinion as to how important an effect they may have on the individual using them for any length of time. Certainly, enough evidence has been obtained now to know that LSD does produce very serious disturbances in the individual. It has led to severe changes in personality structures, emotional confusion, and deterioration. In addition, even weeks or months after the use of the drug has been discontinued, there is a re-entry of the hallucinogenic effect. Reports from large city hospitals such as, the Bellevue Hospital in New York, indicate that there are a good number of individuals turning up with acute psychoses resulting from the unsupervised use of LSD. These individuals have overwhelming fear, uncontrolled violent urges, strong hallucinations, which have led to homicide, and in certain instances have required prolonged periods of hospitalization for treatment.

Treatment consists of using a phenothiazine in adequate dosage to bring about as calming a state as possible, and to reassure the individual, who may be very sensitive and feel that he is in a hostile environment and subject to possible personal injury, even though such does not have any basis in fact.

Marijuana

Marijuana or "pot" is one of the oldest of the psychopharmacological agents, and one that is now most extensively used in modern day youthful society. This agent now smoked as a cigarette, which makes it more potent, was formerly taken in the form of a sweetmeat as hashish. Eating hashish was popular around the middle of the nineteenth century. In the avant garde society, such as occurred in Paris at that time, groups met to eat the drug. Charles Baudelaire, the French translator of Poe, was a very active member of such a group which met at the Hotel Pimodan. His description of the effects which are revealed in his book, *des Paradis Artificiel,* are classic. He described three stages of drug action. The initial phase was hilarity—uncontrollable laughter, giggling, even the most mundane action becoming a subject of great mirth to the intoxicated. This

phase was followed by an extremely increased sensitivity of sight, hearing, touch, and smell, gradually emerging into hallucination. This was followed by sleep, then the next day fatigue, emotional instability, inability to apply oneself, and a severe hangover.

Unfortunately, there is not much accurate data about the dose or the pharmacological action, in spite of its long use by millions of people. In comparison to LSD, marijuana is rather weak. There may occur all the aspects of the LSD action: hilarity, flight of ideas, weakness, increased hearing, heightened visual sensibility, visual and auditory hallucinations, and a disturbed sense of time. There is also an alteration of sensation. For example, the individual may feel that all the flesh has dropped away from his body and that he seems to be walking on his bones. The distortion of time and other senses may also lead to very pleasant hallucinations of vivid colors, and many types and patterns of color and forms. On the other hand, such distortions can bring about a very frightening anxious state in the individual who feels that he is losing contact with reality. This may profoundly affect his emotional structure so that he has a dreadful period of time until the effects of the drug wear off.

Amphetamines

The most dangerous of the recently introduced drugs are the amphetamines, especially methamphetamine and 2, 5 dimethoxy-4-methyl amphetamine (STP). These produce extreme overaction, euphoria, tremors—all the signs of sympathetic overactivity and intoxication—which can lead to extreme elevation of blood pressure, tachycardia and a shock-like state requiring enormous doses of phenothiazines to counteract the effect. The chronic user of the amphetamines may become psychotic, hyperalert, have all the auditory and visual hallucinations, and the tremors which are a hallmark of the action of these drugs.

Glue sniffers are a special problem. Usually adolescent boys apparently cannot resist the tendency to use various solvents for the peculiar euphoria they seem to create. Reports of serious brain damage from this practice are not unique.

The problems presented by the hallucinogenic drugs are considerably different from those of the addicting drugs. These agents, for the most part, do not produce physiological dependence or withdrawal symptoms. They may, however, lead the patient to psychological dependence in that they become a way of life, by helping the patient adjust to underlying emotional tensions or as a means of dulling, changing, or creating an excited sensory state, avoiding social, emotional or other conflicts which may be painful to the individual. They also serve as a means of exhibiting rebellion against parents, authority and society in general. Evidence of this is seen in the hippy movement.

Although some of us are shocked at this movement and the present day behavior of a certain segment of our youth, we should not be. Such signs of rebellion against established society have been with us since ancient times. It has been traced to ancient Egypt. Even Socrates expressed concern about the young men of Athens—their long hair, indolence, disdain for adult values, etc.!! Every century has seen such outbreaks, but as history proves, not all was lost, and the youth as they matured, faced the problems of their day and age as will our youth today.

In talking to the hippies as a member of the Governor's Commission on Drug Abuse, one is struck by the apparent unreality of the situation. Here were highly intelligent youths capable of discussing political, scientific, ethical and moral issues with a high order of significance. But on the surface they were dirty, wore dirty ragged clothing, lived in filthy quarters and seemingly had rejected most of the things our society considers necessary. They admitted they were users of LSD, marijuana and amphetamines but denied need or use of narcotic drugs. They divided drugs into two categories: problem and non-problem drugs. They consider heroin and opium derivatives problem drugs and claim they seldom use them. LSD, marijuana, and the amphetamines, with perhaps the exception of methyl amphetamine, are not problem drugs. They vehemently condemn a society that permits tobacco and alcohol to be advertised while on the other hand, makes such restrictive laws against drugs such as marijuana, which they consider rather harmless.

What is the Answer to Controlling the Spread of Drug Use?

Having interviewed the judiciary, it is apparent that drug abuse problems, already extensive, are spreading. Furthermore, it is involving younger and younger segments of the population. The judges discussed the difficulty in handling these

cases. They said that time and again an unkempt youth, obviously under the influence of a drug, would appear in their courts with all the evidence available. They would sentence him. There would be an appeal, but when the case came to the next court, an entirely different situation would arise. The youth would be clean and alert, presenting a paragon of virtue which would make the next judge wonder what was going on in the first court. This situation, to say the least, is frustrating.

Yet many have expressed fear about the severe penalties for the illegal possession of drugs. After an interview with the Judiciary of the Commonwealth, it was reassuring to know that jurists are careful to use the available laws wisely. Obvious first offenders with a few cigarettes were given suspended sentences or released with a warning. The Federal Bureau of Narcotics report for 1966 shows that of the marijuana violators 70% had prior felony convictions. The average age was 29 years. Only 21% of all convictions were for illegal possession. Only 3% were students, and only one-third of these or 0.8% were indicted for illegal possession. The data leads to the conclusion that the typical violator is a professional criminal nearly 30 years of age engaged in lucrative, illicit drug traffic.

What is the remedy for this situation? First, I believe education is imperative. All youth should know the facts about drugs. The widespread publicity about the harmful effects of LSD has led to a marked reduction in its use, and in time, it will probably be used only occasionally by the far-out individual and by controlled scientific studies for any possible benefits it may have in therapy. Its use now is thought to be less than 5% and about 1% or even less among college students. Although narcotics and other addicting drugs will continue to be a problem they will probably taper off in spite of the current increase in the use of heroin. There will continue to be a few barbiturate and other sedative drugs and amphetamine addicts, but the new laws restricting their sale will prove helpful here.

The future of marijuana is at present uncertain. It is not addicting, but it has properties that make it undesirable. Its use is spreading. It is estimated that at least 30%-40% of the youth in large eastern colleges have used it. Eighty percent have used it only once. About 15% use it during week-ends only, and less than 5% use it to solve emotional problems. It, like most fads, will probably begin to fade as youth becomes interested in other things. Like alcohol and tobacco, it is harmful to society. Alcohol, however, tends to make the subject more extroverted while marijuana tends to make him introverted. This property may, in the end, prove to be the factor that limits its use since our society, unlike certain eastern cultures, is extroverted, and, on the whole, is uncomfortable or impatient with introverted behavior. In other words, as one youngster said, "Who is intereseted in sitting in a corner and seeing pretty colored bubbles when there are so many things requiring action?" As to permanent harm, there will surely be some especially in unstable individuals where a latent psychotic pattern may become aroused or when the drug is substituted for their inability to contend with the problems of life. Firm and just laws administered with wisdom will surely see us through these trying times.

Despite the fact that depression has been recognized for over two thousand years and is the psychiatric diagnosis most frequently made today, there is much about it that remains enigmatic. Paradoxically, although we are still not sure of its cause, it is eminently treatable today. Nevertheless, the disorder continues to be a major health problem; its sufferers number in the millions. It is probable that it has altered the course of millions of lives, and even influenced human destiny. One of its sequels, a constant danger, is suicide. The suicide rate, which is one in ten thousand in the general population, is fifty times higher among depressed persons. All of these facts taken together indicate that it would be well for the physician to know something about this enigma, and its protean manifestations.

Depression in Adolescents and College Students

FRANCIS J. BRACELAND, MD
Senior Consultant
The Institute of Living
Hartford, Connecticut

DANA L. FARNSWORTH, MD
Director, University Health Service
Henry K. Oliver Professor of Hygiene
Harvard University
Cambridge, Massachusetts

When we say that the course of human affairs has been altered at times by depression, this is not hyperbole. It is known that earthquakes, floods, and other calamities have altered human destiny, but it is not as well known that destiny has been altered much more frequently by human emotions. The grandiosity produced by syphilis of the brain, the shallow and erratic emotional states accompanying schizophrenia, or the memory loss and emotional deterioration of cerebral arteriosclerosis, are recognized sooner or later because of the obviously abnormal thinking which accompanies them. There are striking instances in which each of these illnesses has tipped some dramatic national or international event one way or the other.

Due to depression, favorable enterprises have been abandoned because the owner had forebodings of disaster. Important research has been neglected because the investigator imagined difficulties which were not there. Defeat has been

snatched from the jaws of victory because a military commander countermanded a campaign which, in reality, had already succeeded. At a more mundane level, the housewife is too tired to maintain pride in herself or her home; the bright young man with high potential lacks the drive to convert his assets into successful accomplishment. The illness has many more paradoxes. The rich man feels he is poor; the beauty begs for plastic surgery; and depressed people in general are swayed neither by objective evidence, nor by logic.

What is this disorder which causes so much unhappiness? Is it an illness? How is it described, from whence comes it, and what can we do about it? There are many other questions. Is depression a well-defined clinical entity, or is it an exaggeration of mood? Is it quantitatively and qualitatively different from the normal mood, or is it a wastebasket in which diverse, poorly understood disorders are collected? Seemingly, it can be all of these things. Varying degrees and gradations of depression are described, from transient attacks of the "blues," through longer lasting mood changes and symptoms, to graver situations of distressing emotional and mental illness. As the term *depression* is used in everyday life, it implies lowered spirits, feelings of dejection, and a depressive unhappy mood.

The psychiatrist conceives of depression as a disorder characterized by varying qualitative deviations from the behavioral and experiential norm. He may refer to depression as a symptom, in which case he means anguish—a sad, dejected mood. Or he may refer to depression as a syndrome which comprises, in addition to the depressed affect, underactivity, loss of appetite, suicidal ruminations, feelings of hopelessness, insomnia, and other symptoms of a lowered mood disorder. The clinician may go even further and speak of manic depressive disorder or involutional depression, thus referring to the diagnosis of psychotic illness.

All people feel sad, depressed, blue, or melancholy at one time or another. Sometimes the cause is apparent and rational; at other times the emotion seems to "arise from nowhere" and sweeps over the individual in an inexplicable mood of "blackest midnight born". Occasionally, this depressive mood passes as whimsically as it came, and yet again, it seizes upon the individual and cuts him off from activity, from pleasure, and even from his fellow men.

The term *melancholia,* which is one of the great words of medicine and psychiatry, is of ancient origin. It is a relic of ancient influence, dating from the time that depressive spirits were considered to be due to disorders of the bile. In Greek and Roman medicine it was thought that the disease had its origin in an imbalance among body fluids, or humors. The ideal man was one in whom the four humors were mixed in correct proportions. In cases where black bile (melana chole), a supposed product of the spleen, predominated, it gave rise to a melancholy nature. Each nature was thought to be influenced by a planet corresponding to its dominant humor. Legend had it that the soul on its way to earth would receive gifts from the planets as it passed them. Saturn, the coldest, slowest, and farthest from the earth—the evil spirit of the earth's depths—was the patron of the melancholy. Hence, the terms *splenic, saturnine, bilious,* etc. became associated with the melancholic individual.

The first clinical description of the disorder was given by Hippocrates in the fourth century B.C. Aretaeus and Plutarch gave vivid accounts of the disorder, and the cardinal signs of the illness, as delineated today, compare to the descriptions given by these ancients.

The Specific Depressive Reactions

Aristotle once asked the question: Why is it that all outstanding men, no matter how they have distinguished themselves, are obvious melancholics? This question is quite important to us, for it indicates that the term *melancholy* has always had several meanings. On the one hand it describes an illness which disables a man and renders him ineffectual, and on the other hand it describes a quality which seemingly is part of a spiritually creative nature. It is obvious that these last mentioned persons are not sick, nor are they ineffectual. Somberness is their way of life and they have come to terms with it.

What types of depression might adolescents and college students fall heir to, in addition to the above? Well, when an individual becomes psychotic, and the psychosis is distinguished by a depressive mood attributable to some experience, and he has no previous history of repeated depressions, we might say he simply had a *psychotic depressive reaction.* This is differentiated from a *depressive neurosis* by the fact that patients with the latter illness have no impairment of functional adequacy and are not psychotic. If they have repeated depressive episodes, then we must think of *manic depressive psychosis.*

The main signs of depression are generally, but not always, obvious. They consist of a low mood, a loss of interest, a criticism of self or self-debasement, a general slowing up or agitation, varying vague physical complaints, loss of appetite, constipation, fleeting pains, and general bodily symptoms of an overall dejection. Along with this, there is a noticeable loss of zest, lack of interest in things which formerly were attractive, loss of the desire to live, and suicidal ruminations. (It should be remembered that depressions may be hidden under a weltering of physical complaints for which no satisfying underlying disease process can be found.) There is a general slowing up of intellectual processes accompanying the dejected mood, and a slowing up of motor activity. The illness is characterized by withdrawal from previous interests and even from loved ones, yet, there is a regressive action noticeable with increased dependency. Some of the depressive thoughts may become delusional as the individual becomes more indecisive, pessimistic, and vacillating, and he presents a sorry picture as sleep and metabolic functions get progressively out of order.

Briefly, it may be said that these patients are narcissistic and egocentric with many early infantile drives still active. The depressed personality is at the mercy of an extremely severe superego, and is usually overconscientious, overserious, complaining to the point of being subservient, obsessive, and on occasion, overly agreeable. The patient is invariably an individual who finds recognition of his own hostility entirely too threatening to his own security; he cannot allow a vestige of it to appear. He reacts by clamping down too hard and too quickly on any impulse which might in the slightest way betray aggressiveness, and thus he moves along under an unrelaxing constraint from which he eventually begins to suffer feelings of depression.

Some observers see three personality groups most commonly associated with depression. The first react to their hostile, aggressive impulses by an overserious, somber, overstudious, over conscientious pattern of behavior. This pattern, while it aids in the repression of impulses, also depresses the spirits. The second group has developed traits which deny hostility and utilize reaction formation, ie, the unconscious adoption of behavior that reflects impulses opposite to those which the individual is attempting to disown. They are the overly complaining, overly polite, subservient and obsequious types. The third group employs obsessive-compulsive habits (repetitive thoughts or acts provoked by unconscious urges such as, meticulousness, rigidity of behavior, and parsimony) in order to master these impulses. Attempts to desist from this behavior usually result in a vague anxiety and agitation.

Adolescence and Stress

Thus far is the background of the illness. Now consider the person who is to have it—the adolescent, the college student; for as in all of medical practice, it matters as much who has the disease as it does the disease he has.

Adolescence can be defined in various ways. Physiologically, its onset coincides with that of puberty; its conclusion, which cannot be clearly defined, varies among individuals. Emotionally, it is marked by the awakening of sexual curiosity and an intense drive toward independence, and it is completed when psychological maturity resolves the disharmony caused by disordered drives and reason establishes a hierarchy of values.

In the period of adolescence, according to Erikson, the major task is achievement of identity. If this task is not achieved, the result is negative identity. In this stage the person is like a trapeze artist: There is one moment when he is suspended in air—he has left a point of safety and has not yet reached another. What the individual has learned to see in himself must now coincide with the expectations and recognition which others bestow upon him. This is, or should be, the concluding stage of childhood. He subordinates his childhood to new identifications; he no longer looks to the past; the future can no longer be postponed. He searches for a slot reserved for himself in the scheme of things; he must have a clear picture of himself operating within, and belonging to a group.

Adolescents are involved in a struggle with parents and other adults, a struggle whose causes are real when adults fail to allow the adolescents to mature naturally, and when the adolescent fights for things which are already his simply because he is psychologically compelled to do battle. Youth must struggle to be emancipated from both the adult restrictions which might stunt their maturation, and the human tendency to remain secure and maintain the comfort of the known. In this struggle, which is partly with himself and partly with his environment, the youth goes through adjustment phases which are typical in their occurrence and tentative in their outcome. If his patterns

of adjustment are healthy, they will satisfy certain needs. The adolescent must establish an identity which will give him solid ground on which to stand and meet life. Indeed, he must find out who he *is* while the scholastically and vocationally oriented adult world is demanding to know what he wants to *become*. This drive to formulate a personal identity is a core problem. The old affiliations are strained by the conflict between his new attitudes toward himself and others, and their old attitudes toward him. Outstriding and overreaching, he tramples on past relationships. He tends to rebel against all those who would tell him what to do because he confuses obedience with loss of selfhood.

His rebellion and quest for a new personal identity propel the teen-ager into collusion with his peers. Hair fashions, clothing fads, music manias, and dance crazes become for him signs and symbols of individuality, differentiating him from adults while for adults they seem to be exactly the opposite. Behind the masks, the teen-ager works with frenzy to achieve some genuine identity and individuality so that he need not continue to hide and protect himself in this manner. Adolescent styles sometimes shock adults; their fads are sometimes frightening. It is important to understand that they are not the goals of life, no matter how much they may seem to be; they are the means by which teen-agers attempt to achieve an identity.

Adults who fail to see beyond such behavior, the reasons for it, and the needs it may fulfill are usually critical, even though that behavior may be the adolescent's means for arriving at a healthy maturity. An adolescent who is not in conflict with adults at some time is probably not developing properly. Anna Freud, Erik Erikson, and others repeatedly point out that those "model" youths who have no authority conflicts usually have a greater potential for emotional problems than those youths who indulge in argument or antagonistic behavior from time to time.

The adolescent must also develop a sexual identity. An adult's sexual role is to a great extent determined by the sexual orientation of adolescence. During these years the young person is not only unfolding his sexual powers and activities, but is also establishing attitudes about them.

To develop a proper orientation for his masculinity, a teen-age boy needs a father or male figure who presents a healthy picture of what manhood is (a father who is neither a weak, ineffectual person nor a harsh, brutal man), and a mother who is secure enough in her own feminine role to be able to respect her husband's male position and not destroy him in their own relationship, especially in her son's eyes. The teen-age girl needs the same configuration for a proper sexual orientation. Her mother must present for her imitation a healthy and acceptable picture of what womanhood is. She must, therefore, be a psychologically approachable person who is neither aggressive and domineering, nor disenchanted with life in general and her life as a woman, in particular. Similarly, the adolescent girl's father must

Courtesy of the News American.

be sufficiently stable in his masculine role to respect the feminine role of his wife, and thus, implicity encourage his daughter's feminine identification.

We have been reviewing some of the normal conflicts which the adolescent must undergo if he is to reach maturity. Though it is a hazardous and treacherous route, it is the only one which can bring him to the open plains of adult life. The various ways in which adolescents deviate from that route, refuse to travel it, or exaggerate the difficulties encountered constitute the emotional problems and delinquent behavior which disturbed teen-agers manifest.

Everyone, in or out of college, must face stress and cope with it. The essential task of education is learning to overcome handicaps and to use one's abilities as effectively as possible. Certain background factors increase vulnerability to stress. Knowledge of them can decrease their influence and help develop effective methods of dealing with life situations.

Parental conflict or discord, particularly if disagreeing parents try to involve the children in their disputes. Divorce is no more traumatic than a constant state of tension ("cold war", some students call it) between the parents.

Marked contrasts in values between the home environment and those of the college, whether these concern religion, politics, unfair discrimination, or social customs.

Inadequate or improper role models—if the parents or other significant older persons in a child's life show little respect or enthusiasm for intellectual pursuits, he has little reason to do so.

Extreme permissiveness or rigidity or inconsistencies in discipline—without consistent discipline, a child does not know what to expect and can learn little from experience. As one preparatory school boy said to his psychiatrist, "My parents never tell me what to do. They never stop me from doing anything. I don't have freedom like the other boys have."

Improper or inadequate sexual education

Failure of parents to perceive children as separate individuals. Such parents think of their children as extensions of themselves.

Lack of meaning or purpose in what they have been doing. Their rebellion, desirable though it may be, is not always against any definite limits or standards.

Poor study habits—Not having been required to work up to, or near capacity, they don't try to achieve as much as they can.

Factors in College Accentuating Stress

When the young adult goes to college, stress and conflict are inevitable, even necessary, for rapid progress toward maturity. For many of them, it is their first extended period away from home. In the whirl of forces demanding consideration, influences toward developing a life of the mind *versus* anti-intellectual pressures from society and individuals about him, coupled with the necessity of developing appropriate independence and self-reliance, it is no wonder that the college student has difficulty in developing a set of standards and values that are satisfying to him. Students must often cope with such social pressures as, approval of "getting by" on a gentleman's C, strong emphasis on social activities, and many of the attitudes encountered in fraternities and sororities (where there may be more emphasis on grades, than on the learning they should represent).

College students have the usual personal tasks involved in giving up the habits of childhood and youth, while at the same time assuming the responsibilities of the mature adult. In a more rural and restricted environment, this was usually not a complicated process. There were relatively few choices open. One did as the society directed, though choice was possible within narrow limits.

Now all this is largely changed. Opportunities, good or bad, are almost limitless. Instead of certainty, students now face uncertainty. They have incurred the dilemma of choice. An old Dutch proverb clearly expresses the situation: "He who has a choice has a problem." Making a choice would be simple if it were not for the consequences. Each discipline is becoming increasingly complex year by year.

Unfortunately, many college students never have the opportunity to develop a meaningful relationship with any faculty member. An obstacle to more sophomore-teacher discussions is the distaste undergraduates feel for seeking advice. The problem is to get the sophomore talking, and listening patiently and supportively. If grown-ups will only listen, the sophomore will ultimately make good sense to himself.

Attendance at college has been said, by one observer, to be society's most elaborate device for

the artificial postponement of adulthood that could be imagined. But for the student the quandary becomes: "How can I remain effective, feel a sense of meaning and purpose, and yet not know precisely what I am preparing myself to do?"

Depressive Illness in College Students

Sometimes stress is too great, and many students have too few resources for coping with it, and develop serious and disabling emotional conflicts. But many of these conflicts can be treated successfully, and many of them could and should be prevented. Furthermore, recent changes in the social and cultural climate favor the development of a willingness and a capacity to recognize these problems. Recent statistics from college health services indicate that for every 10,000 students, 1,000 will have emotional conflicts of sufficient severity to warrant professional help; 300 to 400 will have feelings of depression severe enough to impair their efficiency; 100 to 200 will be apathetic and unable to organize their efforts—"I can't make myself want to work"; 20 to 50 will be so adversely affected by past family experiences that they will be unable to control their impulses; 5 to 20 will attempt suicide, and 1 to 3 will succeed; and 15 to 25 will become ill enough to require hospitalization.

Walters has recently described a cluster of symptoms which is very common among male college students, and which he refers to as *apathy*. It is expected that every student during the course of his college career will feel apathetic when the pressure of work and his own expectations become too great. There are some students, however, who respond to a transitory stress with prolonged apathy. Such students have a total disinclination to study. They appear to the college officials and to the psychiatrists as indifferent, languid, indolent, lethargic, dull, or apathetic. As one student expressed his plight: "I can't make myself want to study." Such students suffer reduced emotional stability, preoccupation with current work difficulties to the exclusion of past experiences and future expectations, and inability to study in spite of constant efforts. Such students describe themselves as being without feelings other than those of emptiness, physical lethargy, and intellectual impotence. In some colleges the syndrome is known as the "sophomore slump", though it may occur at all college grade levels. Such students, by reason of disturbances in previous interpersonal relations, frequently are compelled to present themselves as weak and inadequate. Their general concepts of competition are unrealistic; they are convinced that they would readily succeed if only they exerted enough effort. In all the case histories studied, there had been actual injury or failure of a successful parent, and to the student, success and competition represented potential personal disaster, similar to that experienced by the parent. It, therefore, became necessary to avoid success, and the unused potential provided a rationalization for the student's failure.

Apathy is a defense that protects the patient or those close to him from being hurt. By living out his fantasies of being deficient, the patient prevents himself from dealing with the effects of his own aggressiveness. His strong feelings of hostility and rage toward certain people are partly diverted to anger toward other persons, and partly inward to himself, producing guilt and "failure". By turning some of his strong feelings outward, seeming to promise success and then turning near-success into failure, the student torments and tantalizes those who help him until they, too, are reduced to a feeling of helplessness as great as that exhibited by the patient.

Apathy may be a precursor of depression, or it may be followed by neurotic symptoms. These patients have never allowed themselves to formulate clear goals, and are committed to nothing. In a sense, apathy is a continuation and an exaggeration of the defenses and solutions commonly used by the adolescent. Such patients have a prolonged adolescence because of unresolved conflicts centering around the formation of a mature identity.

Depression in Women Students.

Women students have many of the same problems as the men display. Suicidal gestures are not uncommon, and should always be taken seriously and investigated thoroughly. Sometimes they call for removal from college; sometimes not. Depression is a common symptom prevalent in young women. They may worry excessively and experience feelings of futility. Some of them use very inappropriate devices to cope with anxiety or depression: suicidal attempts, personal slovenliness, overeating, premature sexual experimentation and excessive and compulsive studying.

Suicide.

The danger which is always in the offing in depressive illnesses is suicide, and it must always

be kept in mind. When persons are going into a depression, and while they are emerging from a depressive illness, the danger of suicide is much greater than when they are in the depths of the illness. When they are deeply depressed, they are often unable to organize themselves sufficiently to carry out their intentions. In hospitalized patients, the greatest period of danger is on weekend leaves from the institution, or shortly after discharge from it. It is thought that the risk in the first six months after hospital release is three times greater than in the general population, and in the second six months, nine times greater.

Attention must be paid to all suicidal ideas; none can be dismissed lightly. Each threat is a call for help, and each one should be looked into thoroughly. Assuring oneself that "he won't do it", "he is a coward", "he has too much to live for", or "it's against his religion" is taking a chance on tragedy. If an individual is depressed enough and desperate enough and sees no future before him, or sees only ruination and disgrace in his path, he is definitely a suicidal risk, no matter who he is or what his belief or position might be.

Whenever a person contemplates suicide, thinks over methods of accomplishing it, considers ways to make the event look like an accident, or determines that the world and, especially his family, would be better off without him, it is obvious that he needs to be under expert care and, more likely than not, needs to be in a protected environment.

Treatment of Depression

Treatment of emotional disorders in adolescents follows the same modes as treatment of adults. For the great majority of adolescents, individual or group therapy brings them through that critical developmental stage in which feeling fuses with behavior, and the individual use of reason seems far distant. For those with severe problems, hospitalization, combined psychotherapy and drug therapy is the usual procedure. We should say at once that we have no "miracle" antidepressant drugs at hand, as yet. Nevertheless, the gain from the use of the drugs we do have is great, and by their usage, depressive attacks in many individuals are shortened, and many depressed patients are able to avoid hospitalization.

Two classes of antidepressive drugs, the so-called monoamine oxidase inhibitors (MAOI) and the tricyclic imipramine-like substances, are equally effective in the proportions 60%-70% of selected patients mentioned above. They also have the same time lag from beginning of treatment, to appearance of improvement—one to three weeks. The four MAO inhibitors in clinical use, which act by indirectly stimulating the central nervous system are iproniazid (Marsilid), isocarboxazid (Marplan), phenelzine sulfate (Nardil), and nialamide (Niamid). Unfortunately, Marsilid is now forbidden in this country because it was said that the side effects were too distressing. The tricyclic antidepressants which are in more common use are imipramine (Tofranil), desipramine (Pertofrane), amitriptyline (Elavil), and nortriptyline (Aventyl). The giving of these drugs and the handling of their side effects is an art.

It cannot be reiterated too often that the deeper and longer-lasting forms of depression are not matters to be trifled with. They require expert attention quickly. Sometimes it seems as though the person who is deeply depressed is more fortunate than the one who is mildly afflicted. The first gets attention and help because of his obvious symptoms, while the latter generally knows only that he feels badly but is not aware of the reason why. Because his symptoms are not so striking, help is slower in coming, and the distressed individual drags about unhappily trying this and that remedy hoping to get relief.

At the risk of being annoyingly repetitive, we need to remind everyone that the prognosis for depressive episodes is good, no matter what is done. The difficulty comes from the fact that the person suffers for so long while waiting to feel better. Therefore, intervention should be sought, both to allay suffering and to protect the patient from harming himself. One need not get depressed contemplating depression in a relative, friend, or patient. Help is at hand and it should be sought out quickly. Depression is now a readily treatable illness and advantage should be taken of that fact. The Dean of Freshmen Students at Harvard made a cogent remark regarding the need for skilled medical and psychiatric help to college students: "With so many wonderful kids on the beach, it pays us to have capable life guards at hand." Meanwhile, we might think of depression as did Leigh Hunt, who said in 1797:

> "If you are melancholy for the first time, you will find upon a little inquiry that others have been melancholy many times and yet are cheerful now."

ΠΟΛΛΩΝ ΆΝΤΑΞΙΟΣ ΆΛΛΩΝ

your medical faculty at work

by John Sargeant
Executive Secretary

The Executive Committee met on March 6, 1969, and took the following actions:

1. Made appointments as follows:

   Maryland State School Health Council—Margaret L. Sherrard, MD, Baltimore County, for an additional three-year term

   Advisory Committee on Foster Care, State Department of Social Services—William M. Seabold, MD, Baltimore city

   Board of Physical Therapy Examiners—(One to be selected for a five-year term from each list submitted to the Governor)—

   Ernest Burch, Jr., Otto Payton, and Barbara Yerger
   William F. Lang, Gilbert Fine, and Ruth Latimer

2. Advised the Maryland Society of Anesthesiologists that it should list names of anesthesiologists who would be willing to serve on the Board of Trustees of Blue Shield, and who would be willing to attend meetings. When the list is received, it will be given due consideration at the next meeting (January 1970) when these appointments will be discussed.

3. Declined to take action in connection with proposed Nurse-Midwife legislation. The Council has previously opposed such action; and there are some problem areas that need discussion. The bill's sponsors are to be asked to meet with Faculty representatives to discuss this further.

4. Declined to participate in a proposed Orient tour as suggested by International Travel Advisors, Inc. of St. Louis.

5. Discussed some mutual problem areas with representatives of the Maryland Nursing Home Association; and deferred the appointment of a special committee or referral of these matters to an already existing Faculty committee until the incoming president can make such a decision.

6. Deferred action in connection with the Social Security Employee Health Program until the Medical Director can meet with the Executive Committee to discuss this further.

7. Deferred action in connection with a proposed Glaucoma Screening Project at Social Security until item 6 can be resolved.

8. Heard that the Maryland Pharmaceutical Association had adopted a policy similar to that of the Faculty's regarding the unethical direct telephone lines between a physician and a pharmacist; and also heard that the C & P Telephone Co. may not legally deny such service to persons requesting it.

9. Heard a report on the Faculty's Medicaid discussions with representatives of the Governor. It would appear that State Health Department statistical data in this area is not valid; and that until such time as valid data can be obtained, no proposals can be made other than having Blue Cross and Blue Shield act as fiscal agent.

10. Authorized the Executive Secretary to investigate the costs involved in consolidating all Faculty pamphlets, publications, etc., into one publication for easier reference by physicians.

11. Heard that Harold P. Biehl, MD, Baltimore, who was recommended to the State Health Commissioner as a candidate for a position on the Maryland Occupational Health and Safety Advisory Board, will be considered when a vacancy occurs.

12. Approved of submitting the name of John E. Adams, MD, Baltimore, as an additional advisor to the Blue Shield Board.

13. Selected Melvin Borden, MD, to represent the Faculty at an AMA sponsored conference on Nursing in Chicago, April 11 and 12, 1969.

14. Agreed to notify the JCAH that it did not provide sufficient time to investigate the question of any "problem situations" in various hospitals in Maryland. A reply was requested within seven to ten days.

    Also agreed to advise JCAH that there may be some problems of which the Faculty is not aware and that more time should be allowed for a response; and suggested that individual hospital staff physicians be given adequate notice of JCAH visits for accreditation so that such individuals may be given an opportunity to talk with JCAH investigators.

15. Agreed not to pursue further the question as to the amount of tax-deductibility a physician could make in connection with the 1968 cruise convention.

16. Authorized Manning W. Alden, MD, Annapolis, and Richard D. Bauer, MD, Adelphi, to attend an AMA meeting on the proposed revision of JCAH standards as representatives of the Faculty.

17. Determined that the 1965 Council ruling is applicable in connection with payment by Blue Shield for laboratory services rendered outside a physician's office.

    > If a clinician and a laboratory share the responsibility for a laboratory procedure, each should send a bill for services rendered. No physician should be denied a reasonable fee for obtaining a specimen for testing purposes and/or interpreting the results of the test, but this should be itemized separately and appear on the physician's statement.

18. Heard that the Nurses Liaison Subcommittee had under consideration the question of performance of medical services by other than those licensed to perform them; and also outside of the scope of currently issued licenses. Another report will be made at a later date.

19. Approved a contribution to the Maryland League of Nursing, as budgeted in the 1969 budget.

20. Approved loan of the portrait of Crawford Long, MD, to be used at the Pratt Library in connection with a Woman's Auxiliary display honoring Doctors' Day.

21. Read the folowing letter from the Faculty's legal counsel into the record of the minutes:

> "I have noted with interest the report of the Executive Committee's work at its January 9, 1969 meeting, including the statement that it 'learned that no insurer for professional liability would cover a physician for any "punitive damages" award.' In order that the Executive Committee may not be deemed to acquiesce on the question as to whether or not a particular policy may cover a particular physician in this respect, I suggest that you put this letter in the Executive Committee's files, so as to indicate that it, while listening with interest to communications made to it by insurance carriers continues to defer to advice of legal counsel in these respects. This should adequately indicate that the Executive Committee and the Medical & Chirurcal Faculty does not necessarily adopt, accept or acquiesce in such a position."

22. Designated the following persons to represent the Faculty at a Public Affairs Meeting in Washington, D.C. on May 17 and 18, 1969: Council Chairman, Council Vice-Chairman, President-Elect and Executive Secretary.

23. Authorized the use of Osler Hall on Sunday, May 25 by the Baltimore Association of Medical Assistants, with that group underwriting any necessary expenses in this connection.

MALPRACTICE ALERT

Physicians in Maryland are reminded they should ensure they are giving statements to AUTHORIZED PERSONS only when discussing any malpractice actions in which they may be involved.

Instances have occurred when insurance representatives of other companies have taken statements from physicians after representing themselves as "the adjuster from the insurance company." In some cases, meetings have been arranged by hospital personnel, with a request to the physician involved to attend. The physician mistakenly believes the meeting to be one in which *his malpractice insurance carrier* is involved. Only too late, he finds he has given information to the hospital insurance carrier which is used to the physician's detriment.

Another cautionary note to physicians, who may be involved in alleged professional negligence, concerns his freely discussing the case with other physicians or persons. In many cases, this can work to the detriment of the physician; not the least of which is the case in which he involves other physicians at a later date.

The above information reflects the importance of a physician judicially discussing any instances of alleged professional liability with which he may be concerned. Should there be any doubt in a physician's mind as to with whom he is to discuss his case, he should make every effort to contact the carrier directly and ascertain the correct procedure to be followed.

MEDICAL NEWS

Norman Levin, MD, chief of the Department of Obstetrics of Lutheran Hospital of Maryland, has been elected president of Lutheran's Medical Staff.

A 1947 graduate of the University of Maryland School of Medicine, Dr. Levin took his residency in obstetrics at West Baltimore General Hospital.

* * *

The newly elected President of the Medical Staff at Mercy Hospital is **Frank A. Faraino, MD. Gerald Galvin, MD,** was elected vice-president and **Robert Mahon, MD,** was elected secretary-treasurer.

* * *

Rennert M. Smelser, MD, was appointed to the Committee on Medicine of The Professional Forum. In this capacity, he will serve a two-year term as vice-chairman for the section on general surgery. **William E. Gilmore, MD,** is chairman.

* * *

James E. Carson, MD, the state mental hygiene commissioner, is hoping to embark this year on a program to house mentally retarded children in residential centers rather than in state hospitals. Dr. Carson said that such centers would provide "a bridge between living at home and being in a larger hospital."

* * *

The **Boards of Trustees** of The Johns Hopkins University and The Johns Hopkins University Hospital announced their approval of the development by Johns Hopkins of a voluntary program of prepaid, comprehensive medical care in the new city of Columbia in Maryland. This decision to proceed was made by the Hospital and University Boards of Trustees at their respective meetings on Tuesday, February 4 and Monday, February 10.

Through this medical plan, Johns Hopkins will develop new methods of delivering high quality health care to a defined population at reasonable cost.

* * *

Paralleling the Columbia activity, Johns Hopkins announced in December plans to join with the residents of East Baltimore to organize a similar form of comprehensive health care or other health care programs which best suit the needs and desires of the local community. **Torrey C. Brown, MD,** assistant professor of medicine, was appointed director of the East Baltimore program. Both the Columbia and the East Baltimore programs of health are under the direction of the newly-created Office of Health Care Programs at The Johns Hopkins Medical Institutions headed by **Robert M. Heyssel, MD.**

* * *

A group of behavioral scientists have launched a unique fellowship program in suicidology, an emerging profession for the study and prevention of suicide. This group from The Johns Hopkins School of Medicine is supported by a five-year, $852,000 grant from the National Institute of Mental Health.

Seymour Perlin, MD, director of the suicidology program and professor of psychiatry, feels that "suicide is a disease of such proportions that it must be considered a public health problem."

* * *

The Johns Hopkins University School of Medicine dedicated and named its new auditorium building on December 6, 1968, in honor of **Thomas B. Turner, MD,** who retired after 11 years as the dean of the Hopkins medical faculty.

The speakers included: **Alexander Heard, MD,** Chancellor of Vanderbilt University; **Dr. Turner,** dean emeritus; **David E. Rogers, MD,** dean of the medical faculty; **Lincoln Gordon, MD,** president of The Johns Hopkins University; and the **Honorable Thomas J. D'Alesandro, III,** mayor of Baltimore.

* * *

In the **first organ transplant to be performed at the University of Maryland Hospital,** a 20-year-old college student received a kidney donated by his mother on December 16. The 2½ hour operation was performed by a transplant team headed by **C. Thomas Flotte, MD.**

Maryland's third kidney transplant patient was discharged from the hospital on January 20. He was the first of three kidney transplant patients in Maryland to resume a normal life.

The first kidney transplant was performed November 1 at City Hospitals and the second, December 8 at The Johns Hopkins Hospital. Almost 2,000 kidney transplants have been performed elsewhere around the world.

* * *

Wilbur J. Cohen, Secretary of Health, Education, and Welfare, announced that the SMI premium rate for the period July 1969 through June 1970 will remain at the present $4.

The Social Security Administration is now meeting with the carriers to determine what additional administrative steps can be taken to keep payment for services in line with the monthly income of $8 per capita derived from premiums plus the matching amount from general Federal revenues.

* * *

As announced last September, the **Hospital Deductible Amount** — the amount for which the Medicare beneficiary is responsible—increased from $40 to $44, effective January 1. Comparable 10% increases are also effective in the dollar amounts as Medicare beneficiary pays toward a hospital stay of more than 60 days or for post-hospital extended care of more than 20 days.

* * *

The **Director of Public Health Service** has announced that the National Institute of Mental Health has unified all its programs in the field of narcotic and drug addiction under one division. Previously, the activities in this area, which encompass research, training, and services were administered by three separate Divisions of the Institute.

To head the Division of Narcotic Addiction and Drug Abuse is **Sidney Cohen, MD, PhD,** a research scientist of international repute who has lectured and written extensively on the subject of drug abuse.

* * *

Med-Chi's Councilors

Richard Y. Dalrymple, MD, took office as Councilor after the 1969 Annual Meeting held earlier this month. Dr. Dalrymple is the chief of surgery at Carroll County General Hospital.

He received his MD degree at Temple University Medical School, and completed his internship at Temple University Hospital in 1940. In 1960 he had finished his surgical residency at Maryland General Hospital.

Dr. Dalrymple

* * *

Dr. Kimble

Acting as a Councilor for the South Central District until 1971, is **Seruch T. Kimble, M.D,** of Silver Spring. Dr. Kimble holds membership in numerous professional and civic organizations, including, the American College of Physicians, of which he is a Life Fellow, the American Medical Association, the Association of American Physicians and Surgeons, and the International Society of Internal Medicine.

Dr. Kimble received his MD at George Washington University, and completed his internship at Presbyterian Hospital in Chicago. After his medical residency at Suburban Hospital in Bethesda, Maryland, he served various posts in the Army. Presently, he is involved in the private practice of internal medicine.

* * *

Robert Johnson Thomas, MD, of Frederick, assumed his duties as Councilor from the Western District after the 1969 Annual Meeting.

Presently, he is an attending surgeon at Frederick Memorial Hospital. Dr. Thomas is a member of the University of Maryland Surgical Society, and serves on the Board of Directors for the Frederick County Cancer Society. He is also a Fellow in the American College of Surgeons and the Southeastern Surgical Conference.

After receiving his MD degree from the University of Maryland School of Medicine in 1959, he completed his internship at Mercy Hospital, and in 1964 he finished his surgical residency at the University of Maryland Hospital.

* * *

Dr. Thomas

Dr. Ball

John G. Ball, MD, will continue to hold the position of Councilor from the South Central District until 1971. He has been a Delegate from Montgomery County since 1950. In 1964 he also held the position of Vice-President of the Faculty. In addition to his active participation in Med Chi, Dr. Ball is a member of various other organizations in which he holds office. He was also President of the Maryland Academy of General Practice for the 1967-68 year.

Dr. Ball received his MD degree from Buffalo University Medical School in 1936, and completed his internship at Emergency Hospital in Washington, D. C. He is a general practitioner in Bethesda, Maryland.

* * *

Is It a Moral or Ethical Issue?

During an interview at the Belvedere Hotel on April 10, Denton Cooley, MD, the eminent heart surgeon from Houston, Texas told inquiring members of the press that he has been involved in heart surgery for 25 years and "has done more heart surgery than anyone else in the world" and therefore feels he is qualified to judge what is best for his patients in the matter of life or death.

Dr. Cooley's method of preserving the life of Haskell Karp of Illinois, by employing an artificial supportive device, is now under investigation by the National Heart Institute at the request of its Director, Dr. Theodore Cooper.

Later that afternoon, Dr. Cooley addressed the audience attending the Scientific Sessions of the Faculty's Annual Meeting. He spoke on the *Experiences with Cardiac Transplantation in Man.* Dr. Cooley quoted Dr. Christian Barnard who said, "Is it moral or ethical to bury an organ which could save a life?"

* * *

Dr. Cooley's lecture will appear in a future issue of the JOURNAL.

Information for Authors

MANUSCRIPTS: Manuscripts will be accepted for consideration for publication with the understanding that they are original, have never before been published, and are contributed solely to the Maryland State Medical Journal.

All manuscripts are acknowledged upon receipt and are followed up by notification of either acceptance or rejection. Rejected manuscripts are returned by regular mail. Accepted manuscripts become the property of the Journal and are not returned. The Journal is not responsible for loss of manuscripts through circumstances that are beyond its control.

Manuscripts should be addressed to: Editor, Maryland State Medical Journal, 1211 Cathedral St., Baltimore, Md. 21201.

SPECIFICATIONS: Manuscripts must be original typed copy, doublespaced throughout (Including text, case reports, legends, tables and references) with margins of at least 1½ inches. Pages should be numbered consecutively.

The manuscript should include the title (brief and concise), the full name of the author (or authors) with degrees, academic and professional titles, affiliations, and any institutional or other credits. Please include a complete address where the author may receive proofs of his article for his approval and corrections.

All manuscripts should be accompanied by a carbon or Xerox copy and the author should retain another copy for his records.

TABLES: Each table should be typed on a separate sheet of paper, be numbered, have a brief descriptive title, and its position in the text should be indicated.

Be sure that statistics are consistent in both tables and text.

REFERENCES: References should be limited to those citations noted in the text, and kept to a minimum of 18. (A complete review of the literature is rarely desirable.) The references must be typed, doublespaced, and are to be numbered consecutively as they appear in the text, with their positions in the text indicated. An alphabetized bibliography is used only when the listing is of books suggested for supplementary reading.

All references must be checked for absolute accuracy. Each journal reference must include author(s) and initials, complete title of article, name of publication, volume, first page of article, and date. Complete dates (month, day, and year) are to be included with all references that have appeared within the last three years. Include with book references name of author(s) and/or editor(s) with initials, title of book, edition, location, publisher, year, volume (if given), and page. If reference is to a chapter within a book, include the author of the chapter (if different from author of the book), and the title of the chapter, if any.

ILLUSTRATIONS: Authors are urged to use the services of professional illustrators and photographers when possible. Drawings and charts should always be done in black ink on white paper. Clear, glossy photographs, black on white, should be submitted and such illustrations numbered consecutively and their positions indicated in the text.

Magnifications will be modified in proportion to the amount of reduction necessary to fit the pages of the Journal. Please do not deface an illustration by writing on the front or the back, nor should it be taped or pasted to paper. The illustration may be pasted onto a piece of cardboard. Attached to the back of each illustration, chart or photograph should be the figure number, the author's name and the title of the article.

Legends for illustrations should be typewritten on a separate page with numbers corresponding to those on the photographs and drawings.

Recognizable photographs of patients are to be masked and should carry with them written permission for publication.

EDITORIAL RESPONSIBILITY: Manuscripts are subject to editorial modification and such revisions as are necessary to bring them into conformity with Journal style.

Statements made or opinions expressed by any contributor in any article or feature published in the Journal are the sole responsibility of the author.

PERMISSIONS: When material is reproduced from other sources, full credit must be given to both the author and publisher and written permission from these sources must be included when the material is submitted.

COPYRIGHT: Material that is published in the Maryland State Medical Journal is protected by copyright and may not be reproduced without the written permission of both the author and the Journal.

COMPONENT SOCIETIES

Prince Georges County Medical Society

The Prince George's County Medical Society has, through its members, expressed its willingness and determination to back Bill No. 149 submitted by Senator Steinberg and now pending the Governor's signature. The Bill which permits doctors, among other professionals, to incorporate their practices has become law in as many as 36 states, and the physicians of Prince George's County were asked to urge the passage of this legislation for the State of Maryland.

In its last meeting, the Prince George's County Medical Society took up and discussed the contention of the Blue Cross of Maryland that the physician who has a laboratory perform work for his patient and then incorporates the change into his fee for service, is acting unethically and therefore refuses compensation. A resolution was passed for the Prince George's County Medical Society to go on record stating that as long as the laboratory charge of the physician to the patient does not exceed the fee charged for the same procedure, directly to the patient, by any other laboratory, the action of the doctor is ethical and in line with the common practice in this area. There was also the opinion voiced from the floor, "that the Blue Cross, an insurance agency, should not concern itself with medical ethics of the physician, but the reimbursement of justified claims to its insured clients."

Baltimore County Medical Association

The Baltimore County Medical Association met at the Greater Baltimore Medical Center on Wednesday, February 19, 1969. The meeting was called to order by the president, Dr. Theodore Patterson. Dr. Patterson thanked Dr. Everett Diggs and Dr. Thaddeus Prout who arranged the scientific program.

Application for Membership: On proper motion, the application of Charles Crimy, MD was approved for active membership.

Committee Reports: Board of Governors—Dr. Venable, chairman, reported a meeting of the Board was held on January 15th at our new headquarters. The carpeting has been installed, the drapes are up, and the secretary has a rented desk. The new furniture will be received sometime in March. At the November meeting, the members approved an expenditure up to $1500.00 for new office equipment, however, it was learned an additional amount will be needed, therefore, the Board approved an additional expenditure of $500.00. The legislative committee planned a dinner-meeting with the Baltimore County Delegation for Monday, February 10th in Annapolis. This was a very profitable "get-together." A Health Careers Day is being planned in cooperation with the Baltimore County Department of Health, the Baltimore County Board of Education, and the Essex Community College to be held on Sunday, May 18th at the college. Medical and paramedical careers will be highlighted. The Board approved an amount up to $100.00 for this purpose. Dr. Hornick plans to conduct a program to test Rubella Vaccine among parochial school children and the Health Department would like the approval of the association. These items were approved by the membership. TABCO (Teacher's Association of Baltimore County) has requested the Board of Education to put in their budget funds to pay for influenza vaccination for teachers in the county. Dr. Snyder moved to approve the influenza vaccine program and motion was seconded. After much discussion, the motion was defeated.

Inter-Agency Council on Smoking and Health: Dr. Barbara Solomon is the representative of our association and she stated the bylaws of the State Department of Education prohibiting smoking on school premises by students has been changed to allow local county option as to whether it will allow smoking in the schools. A letter has been sent recommending that the ban continue in the high schools. Dr. Solomon stated the agency would like a donation of $5.00 from each organization represented in the council so they may buy stationery. On proper motion, the association approved a $5.00 donation for this purpose.

Clarence McWilliams, MD, our representative on the School Insurance Committee of the Board of Education, requested any member who has a complaint about the present school insurance program to contact him following the meeting inasmuch as the School Insurance Committee will be meeting next week.

There being no further business, the meeting was adjourned.

Scientific Program: The subject of the program was "Problems in the Prevention and Treatment of Cardio-Vascular Disease." The introduction was made by Dr. Thaddeus Prout, who was the moderator. "Exercise for Prevention of Heart Disease," William L. Haskell, PhD; "Work Evaluation Unit at GBMC," George C. Roveti, MD; "Problems in the Diagnosis of Coronary Artery Disease," "Gottlieb C. Friesinger, MD; "Case Reports: Cardio-Vascular Disease," Geary L. Stonesifer, MD.

Our thanks to Greater Baltimore Medical Center for an informative and timely presentation.

JOHN M. KRAGER, MD
Secretary

Baltimore City Medical Society

The Board of Directors of the Baltimore City Medical Society met at 1211 Cathedral Street on February 11, 1969 at 4:30 p.m. The meeting was called to order by Raymond C. V. Robinson, MD, President.

The minutes of the January 14th meeting were approved as distributed.

In response to a request for continuation of membership in the Health and Welfare Council, the Board agreed to investigate the activities of this organization before making a final decision.

The Board considered several items of correspondence from the Medical and Chirurgical Faculty. The first dealt with a request for a nominee to receive the Citizen's Service Award. At the suggestion of D. Frank Kaltreider, MD, the Board unanimously selected Mrs. Alexander S. Cochran as its nominee. Mrs. Cochran has been active in the School Board Sex Education Program, has served on the advisory boards of several community hospitals, is active in the Planned Parenthood Association, and exemplifies an earnest unselfish interest in many community humanitarian programs. A list of Mrs. Cochran's services will be forwarded to the Faculty's Public Relations Committee for consideration.

In response to a request from the Med-Chi Nominating Committee for suggestions to be considered by it when preparing a slate for the elective offices of the Faculty, the Board agreed to submit the following:

To serve as five councilors from the Central District—Raymond C. V. Robinson, MD, Robert B. Goldstein, MD, Philip F. Wagley, MD, D. Frank Kaltreider, MD, and James R. Karns, MD.

Delegate to the American Medical Association—John N. Classen, MD
Alternate Delegate—Edward F. Cotter, MD
Member of the Committee on Program and Arrangements—David E. Rogers, MD
Member of the Library and History Committee—Arthur E. Cocco, MD
Member of Finney Fund Committee—Jack M. Zimmerman, MD
Members of the Board of Medical Examiners—Lester Kieffer, MD, Worth B. Daniels, Jr., MD, and John T. Chissell, MD.

No nominees are to be submitted for the offices of President-elect and Vice President. The Board agreed to renominate William A. Pillsbury, MD, as Secretary and Karl F. Mech, MD, as Treasurer.

The President-Elect of Med-Chi requested that the Society submit names which he might consider in making committee appointments for the coming year. However, after consideration, the Board agreed that this was the prerogative of the President-Elect and that if any individual members of the Board wished to make any suggestions these should be sent to the Society office.

Permission to use the Society's mailing list was granted to the Baltimore City Unit of the American Cancer Society with the stipulation that the list not be passed to other groups without the direct approval of the Society.

The recognition afforded Doctors of Osteopathy under the Medical Practice Act makes consideration for their admission as members of the Baltimore City Medical Society mandatory. After much discussion, D. Frank Kaltreider, MD, proposed that the Bylaws of the Society be altered so as to accept Doctors of Osteopathy as active members of the Society. This proposal was referred to the Bylaws Committee for action.

The Faculty Executive Committee, at the request of the Board of Directors, has agreed to allow the Baltimore City Medical Society to hold

its General Meetings on the first Thursday of each month beginning in October. This necessitates a change in the "snow date" policy of the Society which states that meetings cancelled by inclement weather will be held the following week. The Board agreed that in the future the policy will be to hold any meetings cancelled by snow on the following night.

A letter from Mayor Thomas J. D'Alesandro, III, expressing gratitude to the Board for its support and recommendation of the reappointment of Robert E. Farber, MD, as Health Commissioner for Baltimore City was read.

The Community Chest-Red Cross United Appeal headquarters reported that the division in which physicians are classified surpassed its goal for contributions.

Dr. Robinson reported that an agreement had been reached to offer financial assistance in an amount up to $500.00 and some secretarial assistance to the Woman's Auxiliary to the Baltimore City Medical Society. The Board agreed with this arrangement.

Authorization was granted to the Medical and Chirurgical Faculty Medication Committee to investigate charges made against a member of the City Society.

The name of Helen Taussig, MD, was placed in nomination to be considered by the Selection Committee of the American Medical Association as a recipient of the Sheen Award. This award is given for outstanding contributions to medicine and it seemed obvious that Dr. Taussig's achievements would command the respect of the Selection Committee.

The Board agreed that a letter be written to the President of Med-Chi stating that financial support of members of the Society who are in need should be forthcoming, but that prior to such support a thorough investigation of the members' financial status should be made, and the component society should be informed of the pending action.

At the suggestion of the Nominating Committee a letter to all members soliciting suggestions for the various elective offices of the Baltimore City Medical Society will be included in the next mailing. These suggestions will be considered by the Nominating Committee when it prepares the slate of officers for 1970.

Note was made of a letter received from the State Health Department concerning the budget proposals for support of the Medical Assistance Program in Maryland for 1969-1970. The report attached to this letter offers a breakdown of the program and is on file in the Society office.

The Chairman of the Legislative Committee, Howard Moses, MD, met with the Board to present the suggestion made by the Med-Chi Legislative Committee that component societies arrange meetings with their respective legislators. After some discussion, it was agreed that this means of exchanging ideas was probably advantageous in small communities, but that Baltimore City encompasses such a large number of legislators it would be more worthwhile to meet on a personal basis to discuss specific topics.

The Board agreed to circularize the membership in order to update the files in the Society office which are used in making referrals. A questionnaire will be enclosed with the next mailing which all members are requested to return stating whether or not they wish to be included in the Society's list of referral physicians.

The final item on the agenda was a discussion concerning the membership participation in the activities of the Society. The Board expressed a sincere desire to stimulate the interest and participation of the membership in the activities of the Society. Obviously the achievement and fulfillment of any society's goals can only be accomplished by the enthusiastic participation of its membership. Many aspects of this problem are presently under consideration. In reality, however, the reasons for the lassitude are multiple and complex, and the Board would, therefore, be appreciative of constructive criticism and remedial methods offered by the members of the Society.

The meeting adjourned at 6:00 p.m.

DIA-QUEL actually tastes good

DIA-quel contains the only therapeutically active ingredient of paregoric—tincture of opium. This has been combined with homatropine methylbromide and pectin to make a sensible antidiarrheal formula.

By leaving out paregoric's outdated preservative—bitter-tasting camphor—we've produced an antidiarrheal that is good-tasting, as well as effective and prompt-acting in acute, nonspecific diarrheas and their accompanying "cramps." It is DIA-quel, a clear, red liquid with a pleasant cherry flavor.

Each teaspoonful (5 ml.) of DIA-quel Liquid contains:
Tincture of Opium... 0.03 ml.—Equivalent to 0.75 ml. of paregoric.
(Warning: May be habit forming)
To reduce hypermotility and frequency.
Homatropine Methylbromide... 0.15 mg.
A safe dose for mild spasmolysis to curb cramping and griping.
Pectin... 24. mg.
Demulcent, adsorbent. Helps form stools.
Alcohol 10% by volume.

In case you're curious, back in the 1700's paregoric was being used for diarrhea, but since the state of the pharmaceutical art was extremely primitive, fungus growth in the medication was a problem. Bitter-tasting camphor was added to prevent such growth and anise oil was added in an attempt to cover up the camphor taste. DIA-quel Liquid is a modern formulation that does not contain either of these outdated ingredients.

Caution: With use of DIA-quel Liquid observe the usual precautions associated with opium derivatives and anticholinergics.

Dosage: Usual adult dosage: 1 or 2 tablespoonfuls (15 or 30 ml.) t.i.d. or q.i.d. Usual children's dosage (Clark's rule): ½ to 2 teaspoonfuls (2.5 to 10 ml.) t.i.d. or q.i.d.

How Supplied: In 4 fl. oz. (118 ml.) band-sealed bottles.

DIA-quel is a Federally exempt narcotic (Class X) preparation. Where state law permits, no prescription is necessary.

For a complimentary sample of DIA-quel, simply mail your request to us on a signed prescription blank.

The Month In Washington

The American Medical Association told Congress that the Internal Revenue Service acted arbitrarily and completely ignored the facts in imposing a tax on revenue from drug advertising in journals of tax-exempt medical associations.

Bernard D. Hirsh, AMA general counsel, testified before the House Ways and Means Committee, that the relation between the tax-exempt purposes of a medical association, national or state, and the drug advertising in its journal is self-evident.

"Drug advertising alerts and stimulates the physician's interest in new drugs as they become available, and also serves to remind him of the broad spectrum of useful time-proven drugs," Hirsh said. "Obviously physicians should not and do not rely upon drug advertisements as their principle source of information, but drug advertisements often provide an important step in the process through which physicians become educated in the therapeutic value and risks of new drugs and a wider variety of useful drugs. . . . No other advertising provides as much complete and objective information."

Hirsh said the IRS regulations taxing medical associations on their advertising revenues represents an attempt to change the law without congressional action. The IRS officials made a mistake, he stated.

"We urge that this mistake be rectified expeditiously and in the most practical way possible."

Spokesmen for numerous other tax-exempt associations joined the AMA in opposing the tax on their advertising revenues. These included the American College of Physicians, the American College of Obstetricians and Gynecologists, the American Psychiatric Association, the American Dental Association, the Boy Scouts of America, the Girl Scouts of America, the American Chemical Society and the Society of National Association Publications.

Representatives of commercial publishing firms contended in testimony before the committee that the previous tax exemption gave the journals of the associations an unfair advantage in competition for advertising dollars. When the IRS announced the new tax regulations 15 months ago, it stated that the purpose of the regulations was *not* to raise federal revenue but to remove a competitive advantage of the tax-exempt associations.

In an announcement not directly connected with the House committee hearings, the IRS said it also is considering taxing the income tax-exempt associations get from rental of exhibit and display space at conventions.

* * *

A special advisory committee urged the development of an extensive national program to combat alcoholism.

A spokesman for **the National Advisory Committee on Alcoholism** said in an interim report that attention should be given to alcoholism problems in all federally supported health and welfare programs. The committee also recommended:

- Elimination by hospitals of discriminatory policies denying admission to alcoholic patients;
- health insurance coverage for alcoholics;
- increased support for research;
- prevention and control of alcoholism as a vital part of national highway safety programs.

The advisory committee provides advice and guidance to the Secretary of Health, Education and Welfare concerning the department's activities related to alcoholism. Robert Straus, PhD, professor of medical sociology at the University of Kentucky Medical School, is chairman of the committee which was created in October 1966. Its members represent all sections of the country and include experts from the fields of medicine, psychiatry, sociology, vocational rehabilitation, law, and public health.

"The magnitude of the problem is enormous," Dr. Straus stated. "Our country has more than five million alcoholics. Their suffering alone is intolerable, but the need for increased action is made even more imperative by the fact

that affected families may include as many as 20 million Americans."

He also emphasized that alcoholism has a tremendous impact on business, causing absenteeism and loss of productivity.

* * *

The National Institute of Mental Health awarded a first-year grant of $250,000 for a major alcoholism research program at the State University of New York, Downstate Medical Center, New York, N.Y.

The five-year program will include experimental and clinical studies, training, and drug trials. In one study, 60 newly admitted patients between the ages of 25 and 55, with at least a five-year history of alcoholism, will be studied to determine the effects of experimentally induced intoxication and withdrawal on the subjects' sleep patterns, behavior and biochemistry. The investigators will focus upon the mechanisms underlying the development of physical and psychological dependence.

Among the drugs to be tested are haloperidol, dexoxadrol, disulfiram (Antabuse), paraldehyde and chlordiazepoxide. The drugs will be tested alone and in combination with a tranquilizer and an antidepressant.

* * *

The Federal government is planning to launch a five-year, nation-wide program of inoculation against the rubella virus (German measles) as soon as a vaccine is licensed and available in sufficient quantities. The vaccine is expected to be available next fall.

By March 1 of this year two drug manufacturers had announced they had developed a vaccine. Two others were developing one. Merck & Co., Rahway, N.J., was the first to announce completion of testing such a vaccine. The Merck vaccine, which is of the HPV-77 strain, was reported 95% effective in vaccination of 18,000 children and adults. Merck also has been testing a one-shot vaccine against German measles, common measles and mumps.

PEPI Inc., New York, N.Y., said that it had developed a modified live-virus vaccine, also of the HPV-77 strain, for the disease and that, after being licensed, it would be marketed by Philips Roxane Laboratories and Parke, Davis & Co. PEPI said initial production would be primarily a single-dose vaccine for use in pediatric practice, but that later production would include dosage forms suitable for government-sponsored mass-vaccination programs.

The other two companies developing a rubella vaccine are Smith Kline & French Laboratories, Philadelphia, and Eli Lilly & Co., Indianapolis. Eli Lilly has been developing a HPV-77 strain. Smith Kline & French was working on a Cendehill strain. It has proved 95% effective in inoculations of more than 25,000 persons, according to the manufacturer. Another vaccine, using the rubella strain RZ27-3, has been developed at the University of Pennsylvania.

Rep. Ancher Nelsen (R., Minn.) has introduced legislation calling for the same Federal tax treatment of professional corporations of physicians organized under state law as for business corporations.

"We are overdue in acting to guarantee this same right of organization to professional persons that we have always given other forms and types of businesses," Nelsen told the House.

He noted that the Federal government's so-called Kintner regulations, issued in 1960, primarily keyed taxation of professional corporations to state law.

"As a result," he said, "many states, Minnesota included, passed laws enabling incorporation under these regulations. Assuming the air was cleared, many corporations were formed. However, in 1965, the Internal Revenue Service issued new regulations reversing its position, which if upheld, make it almost impossible to create a professional corporation, regardless and in spite of state laws permitting the same.

"No business can operate without some basis of continuity of the ground rules. If any set of rules should be stable, the rules governing the basic tax classification of businesses for tax purposes should be stable and not subject to administrative whim. Businesses, almost without exception—except for the professions with which this bill deals—are now allowed to decide whether to adopt the partnership, association or corporate form under applicable state laws. There is no logical reason for denying this choice to persons who are rendering personal services in the medical or legal fields. Fairness and equity in applica-

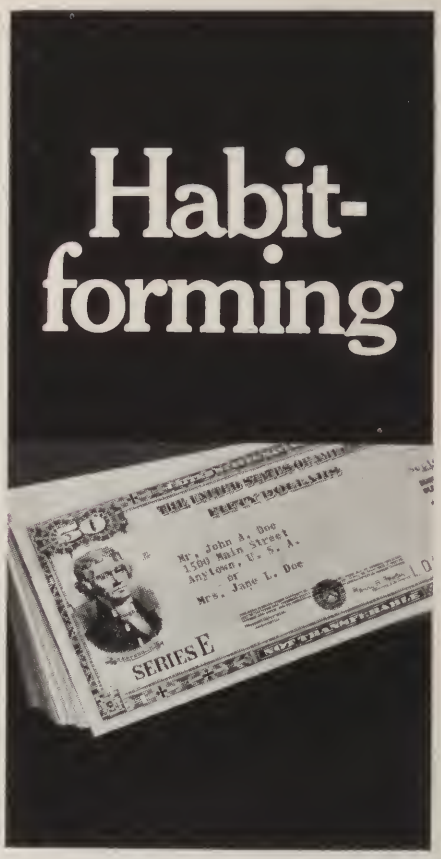
tion of the Federal income tax laws demands that all businesses be treated alike in this sense.

"The only apparent reason for the 1965 amendments to the regulations was to prevent a possible reduction in Federal revenues. I am certainly convinced that this is not an adequate reason for ignoring years of legal precedent and congressional intent in this field. Furthermore, the providing of health, pension and profit-sharing plans through tax incentives under the corporate structure is a worthy objective and a legitimate use of the tax laws. Indeed, I am advised that any possible total tax revenue loss will be minimal when it is realized that most profits will be ultimately taxable, even though such taxation might be immediately deferred.

"The position taken by the Internal Revenue Service in 1965 is untenable. It violates fairness, equity, reasonableness, years of legal precedent, and the intent of Congress as to the tax treatment of business organizations operating legitimately under state law. I would urge all my colleagues to support hearings and passage of this needed legislation at the earliest possible date."

* * *

Sen. Clinton Anderson (D., N.M.) introduced a bill to tie medicare and medicaid payments to hospitals and nursing homes to local Blue Cross allowances. The bill complements a measure introduced by Sen. George D. Aiken, (R., Vt.) earlier this year which ties physicians' charges to Blue Shield schedules. Aiken co-sponsored Anderson's bill. Co-sponsoring both bills are Sen. Mike Mansfield, (D., Mont.) and Sen. Winston L. Prouty (R., Vt.). Anderson co-sponsored Aiken's bill.



Anderson also said he supports the idea of Sen. John J. Williams (R., Del.) that Congress should give medicare and medicaid programs a closer look, perhaps a full-dress investigation.

When you stack one U.S. Savings Bond on top of another, it becomes a habit that's tough to break and hard to beat. That's because it's so painless. Just tell your employer or banker to set aside a regular amount for you before you have a chance to spend it. Sign up today.

New Freedom Shares

Bonus opportunity for people who buy Bonds through the Payroll Savings Plan or Bond-a-Month Plan — a new U.S. Savings Note called Freedom Shares. It pays a higher rate of interest and matures faster. Get all the facts where you work or bank.

U.S. Savings Bonds, new Freedom Shares

his ulcer did not heal...until its surface was cleared of dead tissue and debris

FIRST APPLICATION
ELASE Ointment is applied to a deep ulceration of a finger.

EIGHTEEN DAYS LATER
Healing has progressed rapidly without interruption or interference from any accumulated purulence or necrotic tissue. Greatly reduced size of lesion and minimal scar tissue indicate quality and vigor of healing which is almost complete.

to aid in debridement to facilitate healing in chronic cutaneous ulcers...

Elase® ointment

(fibrinolysin and desoxyribonuclease, combined, [bovine] ointment)

PARKE-DAVIS

By helping to remove dead tissue and debris from the ulcer's surface, ELASE Ointment creates a better environment for the elimination of infection, for healthy granulation...*for healing.* Its lytic enzymes effectively break down DNA in dead leukocytes and other debris...the fibrin in blood clots, serum, and purulent exudates...and the denatured proteins in necrotic tissue. Protein elements of *living* tissue are relatively unaffected. ELASE Ointment is indicated in stasis ulcers and in other infected or inflamed ulcers caused by circulatory disturbances. In cases requiring skin grafting, it is used preoperatively for debridement. For ambulatory patients debridement with ELASE Ointment is a convenient therapy and a regimen likely to be followed. *Precautions:* Observe usual precautions against allergic reactions, particularly in persons with a history of sensitivity to materials of bovine origin or to mercury compounds. *Adverse Reactions:* Side effects attributable to the enzymes have not been a problem at the dose and for the indications recommended. *Discussion:* Successful use of enzymatic debridement depends on several factors: (1) dense, dry eschar, if present, should be removed surgically before enzymatic debridement is attempted; (2) the enzyme must be in constant contact with the substrate; (3) accumulated necrotic debris must be periodically removed; (4) the enzyme must be replenished at least once daily; and (5) secondary closure or skin grafting must be employed as soon as possible after optimal debridement has been attained. It is further essential that wound-dressing techniques be performed carefully under aseptic conditions and that appropriate systemically acting antibiotics be administered concomitantly if, in the opinion of the physician, they are indicated. *Available:* ELASE Ointment is supplied in 30-Gm. tubes containing 30 units (Loomis) of fibrinolysin and 20,000 units of desoxyribonuclease with 0.12 mg. thimerosal (mercury derivative); and in 10-Gm. tubes containing 10 units of fibrinolysin and 6,666 units of desoxyribonuclease with 0.04 mg. thimerosal. ELASE Ointment has a special base of liquid petrolatum and polyethylene; contains sodium chloride and sucrose used during manufacture; is stable at room temperature through the expiration date stated on the package.

Contraindications: History of sensitivity to meprobamate.

Important Precautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use has been reported to result in dependence or habituation in susceptible persons, as alcoholics, ex-addicts, and other severe psychoneurotics. After prolonged excessive dosage, reduce dosage gradually to avoid possibly severe withdrawal reactions. Abrupt discontinuance of excessive doses has sometimes resulted in epileptiform seizures.

Warn patients of possible reduced alcohol tolerance, with resultant slowing of reaction time and impairment of judgment and coordination.

Reduce dose if drowsiness, ataxia or visual disturbance occurs; if persistent, patients should not operate vehicles or dangerous machinery.

Side Effects include drowsiness, usually transient; if persistent and associated with ataxia, usually responds to dose reduction; occasionally concomitant CNS stimulants (amphetamine, mephentermine sulfate) are desirable. Allergic or idiosyncratic reactions are rare, but such reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Previous history of allergy may or may not be related to incidence of reactions. Mild reactions are characterized by itchy urticarial or erythematous maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically as with epinephrine, antihistamine and possibly hydrocortisone. Aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia have occurred rarely, almost always in presence of known toxic agents. A few cases of leukopenia, usually transient, have been reported on continuous administration.

Meprobamate may sometimes precipitate grand mal attacks in patients susceptible to both grand and petit mal. Extremely large doses can produce rhythmic fast activity in the cortical pattern. Impairment of accommodation and visual acuity has been reported rarely. After excessive dosage for weeks or months, withdraw gradually (1 or 2 weeks) to avoid recurrence of pretreatment symptoms (insomnia, severe anxiety, anorexia). Abrupt discontinuance of excessive doses has sometimes resulted in vomiting, ataxia, tremors, muscle twitching and epileptiform seizures. Prescribe very cautiously and in small amounts for patients with suicidal tendencies. Suicidal attempts have resulted in coma, shock, vasomotor and respiratory collapse and anuria. Excessive doses have resulted in prompt sleep; reduction of blood pressure, pulse and respiratory rates to basal levels; and occasionally hyperventilation. Treat with immediate gastric lavage and appropriate symptomatic therapy. (CNS stimulants and pressor amines as indicated.) Doses above 2400 mg./day are not recommended.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. (All tablets also available in REDIPAK® [strip pack], Wyeth.) Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

A Therapeutic Approach to Osteoarthritis

The Arthritis Foundation (Maryland Chapter, 12 W. 25th St., Balto., Md. 21218) is arranging a series of articles by experts on arthritis to appear from time to time in Rehabilitation Notes.

JAMES M. SOWA, MD
Fellow-in-Medicine, Connective Tissue Division
The Johns Hopkins University School of Medicine

Our usual goal of therapy is control of disease and the same goal should be kept in sight for osteoarthritis. Too often the physician, as well as his patient, succumbs to an inordinant pessimism about osteoarthritis and how nothing can be done about structural degenerative changes. Perhaps by broadening our concept of therapy we can introduce a brighter outlook.

A thorough initial diagnostic evaluation is necessary.[1, 2] Rheumatic complaints are often the presenting symptoms of other diseases, or the somatic masks of underlying anxiety states or depressive reactions. It will also become readily apparent that radiological changes are often unrelated to the symptomatic complaints. Indeed, a large percentage of patients with terrible looking X-rays have minimal or no symptoms. When this occurs the wisest course is probably to avoid mention of it and thus not direct the patient's attention to an asymptomatic, although structurally diseased area. In this way your therapeutic efforts may be directed to the primary problem, whether a different disease, osteoarthritis elsewhere, or an underlying emotional disturbance.

In our therapeutic plan[3-8] first must come definite and confident reassurance of the patient about the nature of osteoarthritis. The very word arthritis often conjures up a specter of pain, unsightly deformity, and the cripple in a wheelchair. Just as Stephen Vincent Benet termed rheumatoid arthritis "a mean disease," we might call osteoarthritis a nagging disease. Just the knowledge that his is not a "crippling arthritis" might relieve a patient of enough emotional tension and fear to accept a peaceful coexistence with osteoarthritis. If done early enough, many patients might never require the use of sedatives, tranquilizers, etc., which emotional responses based on ignorance have made so prevalent.

With initial reassurance, therapy is directed toward the body structure and how it affects the disease process. Probably the greatest offender in this regard is fat. For any effective results, the extra stresses and strains upon the skeletal system from obesity must be removed by a gentle, yet firm insistence upon weight reduction. If prominent low back or cervico-thoracic complaints are present, certain temporizing measures may be

necessary until weight is normal. These might include back supports, a good corset to support the flabby abdomen, a well-fitted brassiere for large, pendulous breasts.

Attention to posture, too frequently ignored, may result in alleviation of abnormal stresses and strains acting upon the spine and lower extremities. Good shoes giving proper support to the feet are important. Shearing stresses, so important in damage to the knee, are particularly to be avoided. Looking into activities on the job, at home, and in leisure time is almost certain to reveal a few possible changes. Poor support from chairs on the job or at home, a poorly designed work bench, or poor leverage of instruments might all be corrected. Rather than constantly stand while ironing, the housewife might use a tall stool for part of the time. Does the kitchen have an adequate functionally arranged work space, or must the woman twist, turn, and bend while working for the family? Is the bed too soft? Similar evaluation of leisure habits is necessary. Surely the patient with lumbosacral, hip, or knee disease is only aggravating his problem with golf. The problems pertinent to tennis, bowling, etc., become obvious from evaluating the peculiar stresses each of these activities introduces.

The osteoarthritic patient, in contrast to the rheumatoid patient, finds that activity increases his stiffness and pain. It is amazing how stoic some people become, such as waitresses, enduring great discomfort because of an economically necessary job. Yet continuous work in the face of severe pain is only abusing the joint. Use of rest periods, perhaps an extended version of the popular coffee break, might allow the patient to complete a full work day in comfort. Unless such rest periods can be integrated into the work schedule, an alternative, less taxing job should be considered.

Although rest is necessary, too sedentary a life leads to muscle atrophy and cartilage inanition. An old saying has it that the life of a joint is in motion and this must be preserved. It is the balance of rest with beneficial activity that presents a problem similar to that in the rheumatoid patient. Physical therapy is directed toward maintaining normal motion and muscle strength through therapeutic exercises. Unless the physician has the training and the necessary time for individual instruction, his patient is best referred to a physical therapist. This referral should detail the problem areas and what the physician hopes to accomplish for the best choice of an effective program.

Therapeutic exercises are particularly effective when used with adjuncts such as, moist heat (a hot tub bath) and gentle massage. There is no particular advantage to be derived from much more expensive and time consuming physician-directed modalities such as ultrasound.

In addition to the simple supportive aids mentioned above, another important mechanical measure to relieve abnormal stress is a cane. Occasionally, a brace or crutches will relieve instability and slow further destruction. In some patients, a surgical approach is necessary to give relief. For example, when torn menisci or joint mice produce pain, limit motion, and cause locking of the joint, surgery is an effective and simple therapy. When poor angulation leads to a valgus or varus deformity, a well-timed osteotomy is effective and even preventive therapy. A painful joint, properly selected, can respond to arthroplasty. The hip, frequently a major problem in osteoarthritic patients, is amenable to several effective orthopedic approaches. The key to such patients is a thorough initial evaluation and appropriate consultation.

Diet has little role in osteoarthritis apart from any necessary weight reduction. Because the disease is so prevalent among the elderly, a nourishing high protein and high calcium intake might be beneficial. Vitamin and mineral supplements are unnecessary and a waste of the patient's money, unless specifically indicated.

Lastly in this presentation, and in the care of the patient, are drugs. Most patients will require analgesic-anti-inflammatory drugs. In terms of cost, minimal side-effects, and effectiveness, aspirin is the drug of choice. A regimen of 0.9 gm taken three or four times daily is usually effective. The cheapest of the many preparations available is usually sufficient. Some patients may require a buffered aspirin or an enteric-coated preparation because of gastric upset. With the enteric-coated formulations, obtaining reliable blood levels may be a problem because of poor absorption. An occasional patient may prefer one of the salicylate-phenacetin compounds which are also efficacious. As an adjunct, the analgesic dextropropoxyphene may be used.

In some situations intra-articular steroids, such as prednisolone tertiary butyl acetate, are useful and very gratifying. The benefits of such injections may last from a week to several months with an average somewhere about one month. Dependent upon the situation they may be repeated

as a palliative measure. Too frequent injections should be discouraged. Each is a potential portal for infection. Moreover, when there is a response there is the real danger of overstressing a diseased joint and consequent accelerated destruction. In contrast to intra-articular therapy, at no time should systemic steroids be used in this disease.

There are indications for use of other drugs, particularly among those with severe hip disease and sometimes with spinal involvement. Phenylbutazone is a well-known drug and very effective in hip and spinal problems. For long-term management the dosage should be 100 to 300 mg daily. The physician should require periodic blood counts because of the possibility of bone marrow suppression. Indomethacin is a newer drug, effective in generally the same situations as phenylbutazone, with potent anti-inflammatory and analgesic properties. In a dosage of 25 mg three or four times daily it may be efficacious. The dose may be raised to a maximum of 200 mg daily, but at higher dosage levels headache, gastrointestinal upset, and psychic disturbance become more frequent, especially in elderly patients.

Summary

In a chronic disease with so many extraneous influences as osteoarthritis, a gratifying therapeutic result may be obtained by broadening our definition of therapy. Reassurance of the patient about the non-crippling nature of his disease is a primary factor in alleviating the emotional fears and tensions generated by a diagnosis of arthritis. Secondly, attention to weight reduction, posture, the abnormal stresses of job, home and leisure activities will bring added relief. Judicious use of mechanical aids—from shoes through canes and braces—are another factor. Surgical intervention in the well selected patient affords excellent relief of symptoms. A balance of rest and therapeutic exercise is essential. Drugs are a minor, although necessary adjunct. Aspirin and intra-articular steroids are the primary drug therapies with indomethacin, phenylbutazone and dextropropoxyphene playing important secondary roles.

Admission Rates at Record Level in all Age Groups

Admission rates to Maryland's state-operated mental hospitals increased in all age groups between 1961 and 1967. That is, admissions proportionally increased much faster than the general population. As shown in the following table, rates approximately doubled in all age categories between 15 and 65, and rose at a somewhat lower percentage in the two upper age groups. The total admission rate increased 74.0% (from 193.3 to 336.3 per 100,000 Maryland residents five years of age or older) during this six-year period. Preliminary estimates for the current 1969 fiscal year indicate a further rise in the admission rate to approximately 375.

AGE-SPECIFIC ADMISSION RATES*—FISCAL YEAR

AGE GROUP	*1967*	*1965*	*1963*	*1961*	*CHANGE (1967-1961)*
5-14	23.7	19.5	18.9	16.5	+7.2
15-24	215.9	199.0	184.2	158.4	+57.5
25-44	549.1	438.8	368.7	280.8	+268.3
45-64	511.1	365.8	343.2	235.7	+275.4
65-84	329.2	348.0	325.8	294.1	+35.1
85 & Over	699.7	690.5	745.9	577.7	+122.0
TOTAL	336.3	275.2	248.9	193.3	+143.0
MEDIAN AGE	41.0	40.4	41.2	40.7	+0.3

* Number of admissions per 100,000 estimated Maryland residents in specified age group.

Comparable data have been reported from most other states. Primarily, this upward movement reflects the growth in the number of admissions for short-term intensive treatment of acute nonpsychotic disturbances, together with the increase in the number of patients requiring multiple episodes of care. Schizophrenia and other psychotic disorders accounted for 36.7% of the 5,266 admissions in 1961 and 22.6% of the 11,091 admitted in 1967. During this period, admissions for disorders related to old age decreased from 11.5% to 6.1% while admissions for alcoholism, other personality disorders and psychoneurotic reactions rose from 36.7% to 59.4%. In 1961, 59.4% of all admissions reported no previous psychiatric hospitalization. By 1967 this had decreased to 45.8%. The current rate is 39.1%.

Since the median length of hospitalization of new admissions has been progressively reduced to less than two months, this has not produced a comparable rise in the number of resident patients. Rather, the 74.0% increase in admissions occurred concurrently with a decrease of 5.0% in the average number of hospitalized patients (from 8,428 in 1961 to 8,006 in 1967). The average size of the patient population for the current year is expected to decrease further to 7,425.

Mental hospitals are in a state of transition with a gradual shift from a chronic long-term custodial population receiving minimal care to an acutely ill patient group requiring maximum, high-level professional services. Average daily expenditures per patient must, therefore, be expected to rise further, and a continuing increase in employee-patient ratios is imperative if present treatment levels are to be maintained.

A Service of the Tuberculosis Association of Maryland

tuberculosis

Treatment of Disseminated Mycotic Infections

Amphotericin B was administered in low daily doses over a ten-week period in the treatment of patients with histoplasmosis, blastomycosis, and cryptococcosis. Results are encouraging, and suggest new guidelines for amphotericin therapy.

In an effort to avoid the toxic side effects of therapy with amphotericin B, a new approach to its administration has been tried in the treatment of such mycotic infections as histoplasmosis, cryptococcosis, and blastomycosis. It is based on giving the drug in smaller daily doses and over longer periods of time than is usually employed.

With the objective of attaining daily peak serum levels of amphotericin B at least twice those necessary for *in vitro* inhibition of the infecting fungus, serial amphotericin B serum level determinations were used as guidelines to the daily drug dosage of each patient. Frequent monitoring of the serum levels provided an objective means for regulation of daily dosage, and permitted modification of dosage if associated illnesses complicated the situation or renal function declined.

Fifteen patients with histoplasmosis, blastomycosis, or cryptococcosis were treated by this method. Amphotericin B was administered daily in gradually increasing doses until the desired peak had been reached. The dose was infused slowly over a four- to six-hour period. Heparin was routinely added to each infusion to prevent phlebitis. Blood for serum level determinations was obtained from 45 minutes to an hour following completion of the daily infusion. Peak serum levels persisted for six to eight hours and remained stable when a constant daily dose was established. Sensitivity tests were made regularly.

David J. Drutz, MD; Anderson Spickard, MD; David E. Rogers, MD; and M. Glenn Koenig, MD. *The American Journal of Medicine,* September 1968.

Other Disorders

Five patients had histoplasmosis, three had blastomycosis, and seven had cryptococcosis. All had disseminated disease except for two of the cryptococcosis patients. Eleven had diabetes mellitus but did not take insulin. One patient with histoplasmosis had underlying lympholeukosarcoma and another was receiving adrenal corticosteroid therapy for rheumatoid arthritis. One patient was receiving steroid therapy for sarcoidosis. Other medical problems included Addison's disease in two patients; a seizure disorder and rheumatic mitral valvular prosthesis in one; mild azotemia in four; and congestive heart failure was a complicating factor in four.

Acute toxic reactions were rare. When they did occur, it was at a time when the daily amphotericin B doses were increased or the daily infusion was delivered rapidly.

Eleven of the patients are alive and have been free of infection for periods ranging from 8 to 45 months after a single ten-week course of amphotericin B therapy. Two patients with histoplasmosis have died of myocardial infarction, one during therapy and the other three months after completion of treatment. A third patient was killed in Viet Nam more than two years after successful treatment of extensive pulmonary cryptococcosis. The fourth patient who died had histoplasmosis and was the only one retreated. Post-

mortem examination revealed widespread lymphosarcoma and pulmonary nocardiosis but no evidence of active histoplasmosis.

Results Satisfactory

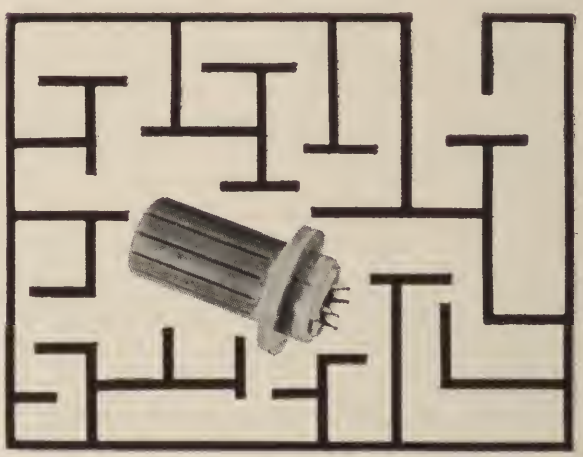
Results achieved with most of the patients indicate that mycotic infections may be treated successfully with relatively small daily doses of amphotericin B and without predetermined goals for total drug dosage. Monitoring of the serum level of amphotericin B provided a guideline, whereby daily dosage could be governed by the sensitivity of the infecting fungus and changes in renal function.

Although the goal of achieving a daily peak serum concentration of amphotericin B at least twice that required for inhibition of the fungus *in vitro* was arbitrary, it was thought that such levels might suppress the infecting fungus and allow host defense mechanisms to control the infection. Experience in treating subacute bacterial endocarditis and tuberculosis had indicated that the duration of therapy was of greater importance than attainment of maximum drug serum levels or specific total drug doses.

The desirability of determining the amphotericin B sensitivity of the pathogenic yeast phase was recognized in the biphasic histoplasma and blastomyces organisms. However, because of various problems, the less fastidious mycelial phase was used in sensitivity tests.

Serum levels in this study were higher than those usually reported for amphotericin B. With drug doses approaching 1 mg per kg of body weight a day, serum levels reached 6.3 μg per ml in one patient. In the one patient who received 1.5 mg per kg per day, a level of 12.5 μg per ml was recorded.

The question has been raised of the possibility of the development of drug resistance with prolonged use of amphotericin B in relatively small doses. However, on the basis of other studies on fungal resistance to amphotericin B, it appears unlikely that fungi resistant to the drug will be a hazard in the regimen discussed.



The relative freedom observed in this study from such acute toxic side effects of amphotericin B as nausea, vomiting, and fever has not been reported in other studies. The most important factor in this decrease in side effects is believed to have been the small daily doses of amphotericin B used.

Toxicity

However, the regimen did not prevent other toxic manifestations. Phlebitis was common and necessitated the prophylactic use of heparin in each infusion. Hypokalemia developed in a third of the patients, and renal function became impaired in each one during the course of treatment. The subsequent return of renal function after completion of therapy suggests that the degree of permanent renal damage resulting from amphotericin B administration is a function of the total dose administered. Thus, the present treatment regimen may produce less permanent impairment of renal function than other regimens.

Anemia was another occurrence and red cell aplasia developed in two patients during therapy, but red cell production returned to normal after amphotericin B therapy.

On the whole, the therapeutic results with this regimen have been encouraging. The laboratory studies involved are simple and easily taught to technicians with minimal mycological training. The approach provides a rational basis for therapy and allows treatment of patients with impaired renal function and other severe underlying medical disorders.

HISTO IS CONFUSING.

Histoplasmosis can mimic such unrelated diseases as TB, leukemia, pneumonia and syphilis. Use the blue Histoplasmin LEDERTINE™ Applicator as the first step in differential diagnosis and as a routine step in physical examinations for the permanent records of your patients.

HISTOPLASMIN, TINE TEST

(Rosenthal)

Precautions—Nonspecific reactions are rare, but may occur. Vesiculation, ulceration or necrosis may occur at test site in highly sensitive persons. The test should be used with caution in patients known to be allergic to acacia, or to thimerosal (or other mercurial compounds).

Baltimore City health department

Dr. Ann Webb Appointed Clinical Director For Handicapped Children

Ann H. Webb, MD, has been appointed clinical director for the Division of the Handicapped in the Child Health Services section of the Baltimore City Health Department.

Dr. Webb will be responsible for the evaluation and follow-up of handicapped children referred for assistance to the department by private physicians, hospitals, public health nurses, schools, and other city agencies. She will work in close cooperation with the Bureau of School Hygiene and other personnel in the Bureau of Public Health Nursing and the Child Health Services section.

Dr. Webb has been a part-time school physician for the past two years. In addition to her school health work she has assisted in the Division of the Handicapped for the past six months.

Educated in the schools of New York city, Dr. Webb, a graduate of Vassar, received her MD from Columbia University College of Physicians and Surgeons in 1964, and during that time received a two-month Public Health Service grant to study the public health aspects of tropical medicine in Surinam, Dutch Guiana. Prior to coming to the Health Department, she received pediatric training at the University of Virginia Hospital in Charlottesville and the Mary I. Bassett Hospital in Cooperstown, New York.

The City Health Department's Division for the Handicapped registered 1,575 children during the past year and now has on its rolls a total of 26,781 since this program began in 1956. The division is under the supervision of John B. Saratsiotis, MD, director of the Bureau of School Hygiene in the Baltimore City Health Department.

Evaluation Report Of Medical Aspects Of Early School Admissions Program

An evaluation of the City's Early School Admissions Program of the Baltimore city public schools has been conducted by Science Research Associates for the school year 1967-1968 and this past summer. Some excerpts of this report are as follows:

> A comprehensive health and medical program was provided by the Baltimore City Health Department in conjunction with a recently organized Comprehensive Medical Services program for indigent children. Full range medical, dental nursing, and psychological, diagnostic, preventive, and remedial services were included. . .
>
> Judging from teacher, principal, and parent comments during interviews, it appears that the health and medical services, provided Early Admissions children, were identified as the best of the ancillary services.
>
> Because of the comprehensiveness of the program, a detailed analysis is beyond the scope of this evaluation. However, a report of the health services provided indicates the scope and quality of the program. The Bureau of School Hygiene is to be commended for the excellent coordination and use of many community resources. . . . Included, in addition to what is usually provided in health and dental programs, were Mental Health teams who were active throughout both summer and winter programs.

The Early School Admissions Program was inaugurated in 1962 as a special three-year educational program financed jointly by the Baltimore city public schools and the Ford Founda-

tion. This was continued in 1966 with the financial assistance of the Federal Elementary-Secondary Education Act. Up to now a total of 6,000 children have benefited from this program.

The aim of the program is to enrich the lives of culturally deprived four- and five-year-olds through overcoming academic handicaps which face them on entrance into the elementary school program. Central to the success of this program is home, parental and community participation.

The Early School Admissions Program was a forerunner of the Federally funded national Head Start program of the Office of Economic Opportunity which was based in large measure on Baltimore's experience. Mrs. Catherine Brunner is supervisor of Early Childhood Education in the Baltimore public schools and Dr. Saratsiotis directs the school health program, a responsibility of the Baltimore City Health Department.

Opportunity is afforded here to express thanks to the many physicians and others who are participating in this program.

Wolff-Parkinson-White Syndrome

Wolff, Parkinson, and White first defined the syndrome which bears their names, and sometimes called the pre-excitation syndrome, as a clinical and electrocardiographic entity in 1930. They described 11 patients whose electrocardiograms showed a relatively short P-R interval with a slurred and widened QRS complex, usually followed by an abnormal T wave, and having a tendency to paroxysmal tachycardia. This combination of electrocardiographic abnormalities had been described earlier, but without the associated episodes of paroxysmal tachycardia.

JOHN J. MESSINA, MD
Instructor in Medicine
Director, Adult Cardiac Clinic
University of Maryland School of Medicine

The Wolff-Parkinson-White syndrome (W-P-W) has been the subject of numerous publications, but there has been no unanimity of opinion regarding its cause. Most writers agree that the most tenable hypothesis is that of ventricular pre-excitation via an anomalous or accessory atrioventricular pathway. Kent described such accessory pathways in rabbits, mice, and other animals as early as 1893. In 1932, Holtzman and Scherf, and, independently, Wolferth and Wood, postulated that the pre-excitation syndrome was best explained on the basis of an accessory pathway, although such a pathway had not been described previously in man.

In 1943, Wood and Wolferth demonstrated an anomalous atrioventricular muscular bundle (Bundle of Kent) in a young man who had had the pre-excitation syndrome and who had died during a paroxysm of tachycardia. Numerous reports of accessory atrioventricular bundles in persons with a history of the W-P-W syndrome have since appeared in the medical literature.

Age and Incidence

The W-P-W syndrome has been reported in all ages from early infancy to advanced age, although it initially was thought to be found primarily in otherwise healthy young adults. In newborns and infants, the diagnosis is definitive only if the typical deformity (the delta wave) of the QRS is present, because short P-R intervals are normally seen in this age group. The incidence of this syndrome is not known with certainty, but most authors agree that it is approximately 1.5 per thousand EKG's in a hospital population.

The even distribution of the W-P-W syndrome in all age groups favors its being a congenital variation, although nothing definite is known about hereditary factors governing its occurrence. A relatively high incidence of associated thyrotoxicosis has been reported, and the W-P-W syndrome also has been frequently associated with congenital cardiac defects, notably, Ebstein's Anomaly. Ap-

proximately 60-70% of reported cases occur in males.

Characteristics of the W-P-W Syndrome

The electrocardiographic criteria of a classical case of the W-P-W syndrome are:

1. A short P-R interval (0.10 sec. or less, in 85% of cases);
2. A prolonged QRS complex (0.11-0.12 sec., in greater than 50% of cases);
3. Slurring and slow rising of the onset of QRS complex in some of the leads. This is termed the delta wave, and is the most characteristic feature of the EKG;
4. Deviation of the RS-T segment and T-wave changes, and
5. A tendency to paroxysmal tachycardia (occurs in 12-80% of reported cases).

Mechanism

It is thought that the short P-R interval is due to the shorter distance between the S-A node and the accessory A-V bundle, as compared to the distance between the S-A node and the A-V node. The delta wave is thought to represent premature arrival of the wave of activation at the ventricles (ventricular pre-excitation). It, along with the prolonged QRS complex (often resembling right or left bundle branch block), is thought to represent an abnormal spread of the wave of activation (other than via the bundle branches and Purkinje system) through the ventricles. The RS-T segment and T wave changes are thought to represent aberrant ventricular repolarization.

The mechanism responsible for the frequently observed tachyarrhythmias is obscure. The re-entry phenomenon has been postulated by some investigators. In the case of paroxysmal atrial or A-V nodal tachycardia, a paroxysm of rapid heart action may be precipitated by passage of the ectopic atrial or A-V nodal impulse downward through the A-V node and its subsequent return to the atria or A-V node via the accessory pathway, thus constituting a form of re-entry. The paroxysmal tachycardia will persist if the re-entry phenomenon is repetitive.

Either normal or anomalous ventricular complexes may be seen when atrial fibrillation, atrial flutter, or paroxysmal atrial tachycardia are present in the W-P-W syndrome, since the electrical impulse may be conducted through either normal or accessory pathways. Usually, the more rapid ventricular rates are associated with anomalous QRS complexes, since the impulses arrive at the A-V node at a rate faster than the normal A-V nodal pathway is capable of conducting.

Prognosis

The W-P-W syndrome is usually benign, and there are no subjective manifestations or hemodynamic disturbances resulting from ventricular pre-excitation itself. However, paroxysmal tachycardia may occur at any time (during rest, exercise, or emotional upset), and sudden death during such an episode has been reported. Life insurance experience indicates that applicants with this syndrome are not standard risks, since their mortality rate is said to be approximately three times as great as that of individuals without the W-P-W syndrome.

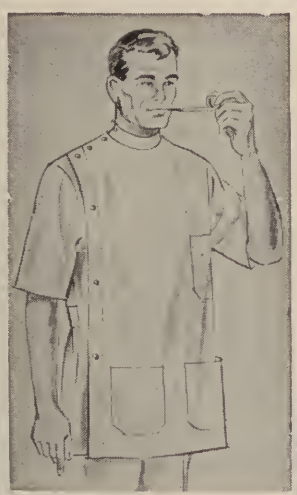
Differential Diagnosis

The W-P-W syndrome is unique in that the diagnosis is made only by means of an electrocardiogram. Although easily recognizable in its classical form, it is misdiagnosed by physicians who initially see the patients, in approximately 30–50% of cases. Most often, the electrocardiograms are misinterpreted as acute myocardial infarction (especially inferior and anterior), left ventricular hypertrophy, or bundle branch block (right or left). It is also possible for the electrocardiographic features of myocardial ischemia or infarction to be masked in the presence of W-P-W syndrome.

Treatment

No specific treatment, aside from the avoidance of factors known to precipitate paroxysmal tachycardia, is required for the W-P-W syndrome during periods of normal sinus rhythm. Some authors, however, advocate the prophylactic use of quinidine, and more recently propranolol has been reported to be successful in preventing paroxysmal tachycardia. It is extremely important to unmask the electrocardiographic features of myocardial ischemia, myocardial infarction or ventricular hypertrophy when these are present. This is accomplished by conversion of the pattern of anomalous conduction to normal A-V conduction by such measures as cartoid sinus pressure, Valsalva maneuver, exercise, amyl nitrite, atropine, and quini-

dine. In general, the sinus tachycardia caused by amyl nitrite, atropine, and quinidine tends to abolish anomalous conduction whereas digitalis, neosynephrine and prostigmine may increase or precipitate it.



For treatment of paroxysmal tachycardia (especially atrial fibrillation with a rapid ventricular response). However, quinidine is the drug of choice. Since a combination of quinidine and digitalis may be used, quinidine acts to depress the anomalous pathway and digitalis the normal one. Vasopressors also have been used successfully in terminating the paroxysms of tachycardia, and more recently cardioversion has been found to be effective as well.

In view of the generally good prognosis when there is no associated heart disease, such patients with the W-P-W syndrome should be reassured concerning their condition, since they may suffer more from the electrocardiographic diagnosis (and sometimes mis-diagnosis) than from the anomaly itself.

WILLIAM J. PEEPLES, MD, MPH, COMMISSIONER

Maryland State department of health

Highlights

Medically Indigent Restored to Medicaid Program

The Hon. Marvin Mandel, during his first week as governor of Maryland, issued a directive to the department to restore 22,000 medically indigent persons to the Medicaid Program who had been previously enrolled. The Health Department is delighted with this action and Commissioner Peeples has written a letter to Governor Mandel expressing this sentiment.

The governor's decision is an excellent one for several reasons: From the humanitarian standpoint, this is a very needy group and removal from the Medical Assistance Program has resulted in many cases of great hardship; this is also a definitive contribution to preventive public health and constitutes a long-range and enlightened economy.

As Dr. Charles Mayo said originally, and many have repeated since, "Sickness makes people poor, poverty makes people sick." The Governor's decision is a timely step in the direction of interrupting that cycle.

The department, in close collaboration with the Department of Social Services, is now making the necessary plans to get the machinery in motion to carry out the Governor's directive. It will be necessary for this group of individuals to reapply to their local Department of Social Services for reinstatement in the Medicaid program. This will take some time, but it is being expedited as quickly as possible.

Since July 1, when Medical Assistance was canceled for 22,000 people, plus those who were eligible but have an income above Maryland's "indigency" level, numerous inquiries and protests have been registered with the department. More than 1,500 telephone calls and almost 100 letters have been received from patients, their legislators, or others seeking help on the behalf of the indigent sick. In an effort to undersand why their needed medical care should not be provided, 432 patients visited the department and made pleas for special consideration.

1970 Fiscal Year Budget

The 1970 fiscal year allowance for the entire department totals $129,252,945 as opposed to the current 1969 fiscal year appropriation of $103,-911, 269.

The department requested $99,872,712 for Medicaid in 1970. The printed budget allows $68,230,-380. The 1969 appropriation is $50,164,821.

The amount allowed for Preventive Medical Services in the printed budget is $1,522,239. It should be noted, however, that much of the activities of the 24 local health departments are of a preventive nature, for example: family-planning clinics, maternity clinics, child health conferences, day-care centers, tuberculosis and venereal disease control activities, and other similar programs.

The amount estimated for community health services for the current 1969 fiscal year was $26,408,524. The estimated amount for fiscal year 1970 is $30,350,261.

State Executive Reorganization Proposed

An administration-backed bill submitted to the 1969 General Assembly would enable the Governor to select a Secretary of Health who would oversee the coordination of the present departments of health and mental hygiene, along with

25 boards and agencies, into one Department of Health and Mental Hygiene.

The reorganization also calls for the Secretary of Health to supervise the activities of the Department of Juvenile Services. In presenting the legislation, Governor Mandel said, "Juvenile delinquency should not be treated as a criminal problem, but as a health problem. Our handling of juvenile delinquency as a criminal problem just has not worked."

If the bill is enacted as submitted, the present State Board of Health and Mental Hygiene would be replaced by the Secretary of Health and a board of review.

The new secretary's responsibilities would include internal management of the department, establishment of areas of responsibility for budget presentation and expenditures, the appointment of a deputy secretary, and a general council, subject to the approval of the Governor. Also, he would be in charge of appointing and dismissing personnel.

The Board of Review would be composed of seven members serving staggered three-year terms. Three of the board's members would be experienced in the fields under the new department's jurisdiction. Four members would represent the public directly. All would be chosen by the Governor and would serve without pay.

The board members' duties would be to advise the secretary on the administration and operation of the department, and would hear all appeals to rules and regulations set by the department.

At this time, there are no indications of the expenditures necessary to implement the reorganization plan.

Nose clear as a whistle

(THANKS TO DIMETAPP®)

Dimetapp Extentabs® does an outstanding job of helping to clear up the stuffiness, drip and congestion of colds and upper respiratory allergies and infections. Each Extentab keeps working up to 12 hours. And for most patients drowsiness or overstimulation is unlikely. Try Dimetapp. It clearly works.

UP TO 12 HOURS CLEAR BREATHING ON ONE TABLET

Dimetapp Extentabs®

Dimetane® (brompheniramine maleate), 12 mg.; phenylephrine HCl, 15 mg.; phenylpropanolamine HCl, 15 mg.

FOR UPPER RESPIRATORY ALLERGIES AND INFECTIONS

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripheral vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

A.H. ROBINS COMPANY
RICHMOND, VA. 23220

A·H·ROBINS

Mild ulcerative colitis may be triggered here...

In mild ulcerative colitis, a number of factors can precipitate an attack: for instance, dietary indiscretion, such as eating raw foods, or emotional overreaction, such as that aroused by financial difficulties. No matter what causes the patient's sensitive colon to "act up," he soon suffers from acute discomfort...and often, from anxiety and apprehension as well. Such patients frequently respond well to adjunctive dual-action Librax® therapy.

Librax combines, in a single convenient capsule, the well-known antianxiety effect of Librium® (chlordiazepoxide HCl) and the dependable anticholinergic/antispasmodic effect of Quarzan® (clidinium Br). Therefore, as Librax helps to relieve the patient's excessive anxiety and reduce his overreaction to stress, it also, at the same time, helps to control hypersecretion and hypermotility, thus relieving spasm and abdominal discomfort.

With Librax, the dosage schedule is simple: 1 or 2 capsules, t.i.d. or q.i.d., will in most cases bring the patient significant relief of both the emotional and physical elements that contribute to his psychovisceral disorder.

Before prescribing, please consult complete product information, a summary of which follows.

INDICATIONS: Indicated as adjunctive therapy to control emotional and somatic factors in gastrointestinal disorders.

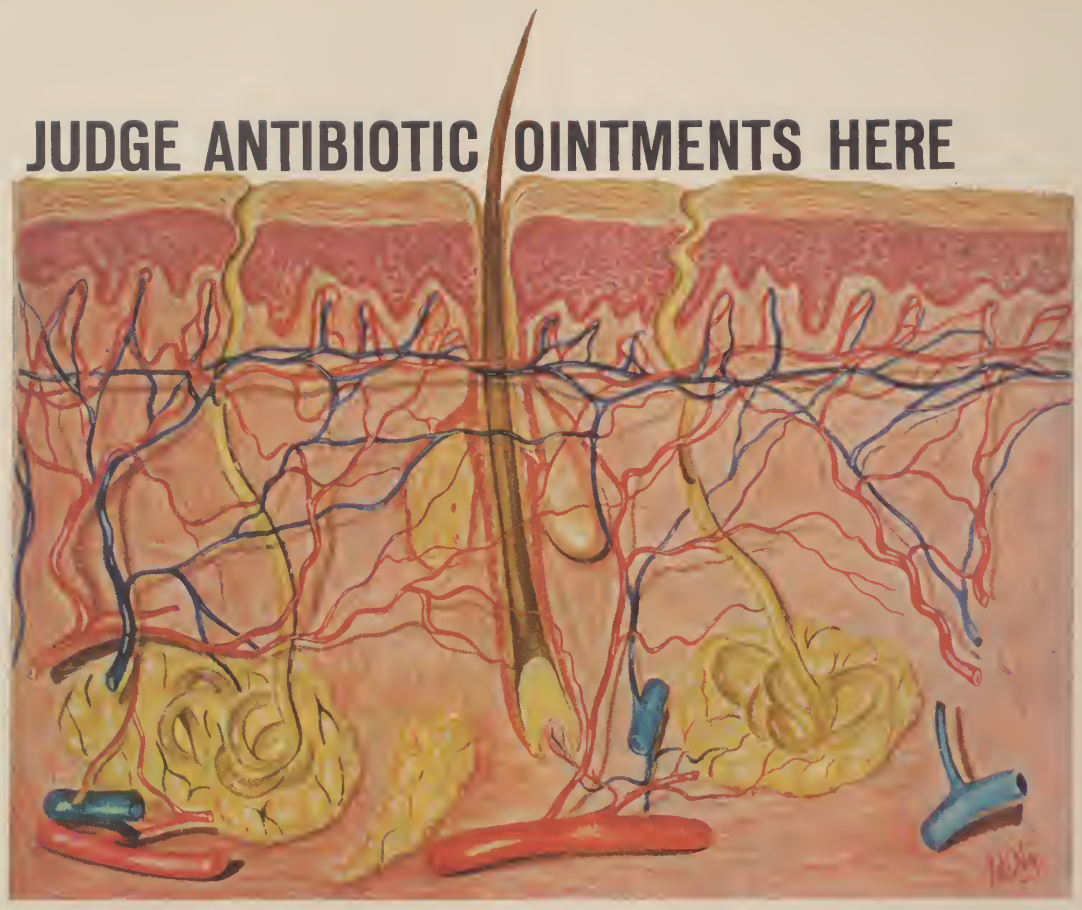
CONTRAINDICATIONS: Patients with glaucoma; prostatic hypertrophy and benign bladder neck obstruction; known hypersensitivity to chlordiazepoxide HCl and/or clidinium bromide.

WARNINGS: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering Librium (chlordiazepoxide hydrochloride) to known addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards. As with all anticholinergic drugs, an inhibiting effect on lactation may occur.

PRECAUTIONS: In elderly and debilitated, limit dosage to smallest effective amount to preclude development of ataxia, oversedation or confusion (not more than two capsules per day initially; increase gradually as needed and toler

or here.

ate Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.



ADVERSE REACTIONS: No side effects or manifestations not seen with either compound alone have been reported with Librax. When chlordiazepoxide hydrochloride is used alone, drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally with chlordiazepoxide hydrochloride, making periodic blood counts and liver-function tests advisable during protracted therapy. Adverse effects reported with Librax are typical of anticholinergic agents, *i.e.*, dryness of mouth, blurring of vision, urinary hesitancy and constipation. Constipation has occurred most often when Librax therapy is combined with other spasmolytics and/or low residue diet.

two good reasons for prescribing LIBRAX®

Each capsule contains 5 mg chlordiazepoxide HCl and 2.5 mg clidinium Br.

ROCHE
LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

JUDGE ANTIBIOTIC OINTMENTS HERE

Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Complete literature available on request from Professional Services Dept. PML.

POLYMYXIN B-BACITRACIN-NEOMYCIN OINTMENT

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

Emergency Medical Services

Alarm over the explosive increase in highway slaughter impelled Congress to pass the National Highway Safety Act in 1966. The Act requires States to meet minimum standards in 16 different areas affecting highway safety or forfeit 10% of the State's federal highway money (which could be as much as $7,000,000 in Maryland).

PERRY STEARNS, MD
Medical Consultant to the
Emergency Health Services Program,
Maryland State Department of Health

State Emergency Medical Services should reach minimum standards by 1971. Specific goals are:

1. Training and licensing of ambulance and rescue personnel.
2. Specifications for type and number of emergency vehicles, including supplies and equipment which shall be carried.
3. Requirements for the operation and coordination of ambulances and other emergency care systems.
4. First aid training programs and refresher courses for emergency service personnel and first aid courses for the general public.
5. Standardized two-way communications.
6. Standardized procedures for summoning and dispatching aid.
7. An up-to-date comprehensive plan for emergency medical services including: facilities and equipment, defined areas of responsibility and agreement for mutual support and communications systems.
8. Periodic evaluation of services and plan.

Emergency Medical Services (E.M.S.) includes ambulances, rescue squads, and emergency care facilities. Its responsibility ends at the hospital when the patient is delivered to the care of a physician. E.M.S. cannot prevent accidents but E.M.S. *can* prevent some of the deaths and disability resulting from accidents.

In 1968, Maryland had 867 fatalities resulting from 754 motor vehicle accidents. There were 54,325 reported injuries as a result of 94,513 accidents. No one knows how many deaths or disabling injuries could have been prevented with better ambulance service.

MRS. HARRY L. BERMAN, EDITOR

Auxiliary Adjourns

The Woman's Auxiliary to the Medical and Chirurgical Faculty of the State of Maryland adjourned this month, concluding one of its most progressive years. In addition to continuing ongoing projects and activities of past years, Mrs. H. Leonard Warres, the outgoing president and her able Board initiated and put into work a number of new health-related programs.

An Ad Hoc Committee on Youth and Violence was organized under Mrs. Howard Biehl to join forces with other groups interested in combating violence on radio, television, and in the movies along with a massive letter-writing campaign calculated to reach producers in these media. Our Annual Meeting speaker and panel focused on this new area of national concern.

A survey on how involved our members are in various productive activities, professions and services, and one concerned with statewide unmet needs of the elderly and shut-ins relating to home care such as "friendly visitors" and "meals services" were chaired with impressive results by Mrs. G. Allen Moulton.

Excellent Health Education presentations in the form of "Package Programs" were distributed to community groups for showing and discussion, covering such subjects as Teenage Venereal Disease, Youth, Health and Fitness, Mental Health of Children, Health Careers, Immunization, The Block Mother Plan, Homemaker Service and Sex Education.

The Auxiliary helped finance a new nurse recruiting film which has been selected for viewing at the National AMA Auxiliary at the Waldorf Astoria Hotel in July on the basis of its excellence.

Other promising "firsts" for the Auxiliary were the conducting of state-level workshops paralleling their national counterparts, covering all of the aspects handled at the Eastern Regional Workshops in Boston, and the enlistment of translation teams in communities outside Baltimore, in accordance with a proposal from Faculty members, to facilitate communication between physicians and patients unable to speak English. Credit must be given to the County Presidents and their Chairmen for their efforts in reaching those able and willing to communicate in various tongues.

In the interest and promotion of Health Careers, Mrs. Robert J. Dawson, State Health Careers Chairman, made significant progress in stepping up financial assistance to those wishing to go into paramedical fields. Scholarships given out this year surpassed last by an increase of over double. Harford County, although geographically small, initiated a big slide project with commentaries showing all the promising and rewarding opportunities available to young people there.

In the area of local Community Service, Mrs. Leland B. Ransom of Allegany County launched a first Family Life Program presenting well-

attended sessions on Sex Education of Children. Mrs. Louise Graff, Chairman of Community Service, Press and Publicity, Washington County, performed outstandingly in assembling and displaying ancient and historic memorabilia of that county's medical background.

The necessary task of revising the Bylaws was successfully undertaken by Mrs. Emerson C. Walden, Revisions and Resolutions Chairman. In other areas of auxiliary activity gainful work by Chairmen and committees were duly noted.

Last to be mentioned here, but far from least, three state-wide money-raising projects under the competent leadership of Elizabeth Linhardt, AMA-ERF Chairman, were completed with substantial gains for the ERF treasury. With each county participating in the Day at the Races the net amount raised was $616.20. Mini-shares, Christmas card sales and Doctors' Rose Bush returns have not had a final count at this writing.

A fond farewell to an industrious team and a salute to its successors!

In the complex picture of moderate to severe anxiety...

there is a new reason for prescribing Mellaril (Thioridazine HCl)

effectiveness in mixed anxiety-depression

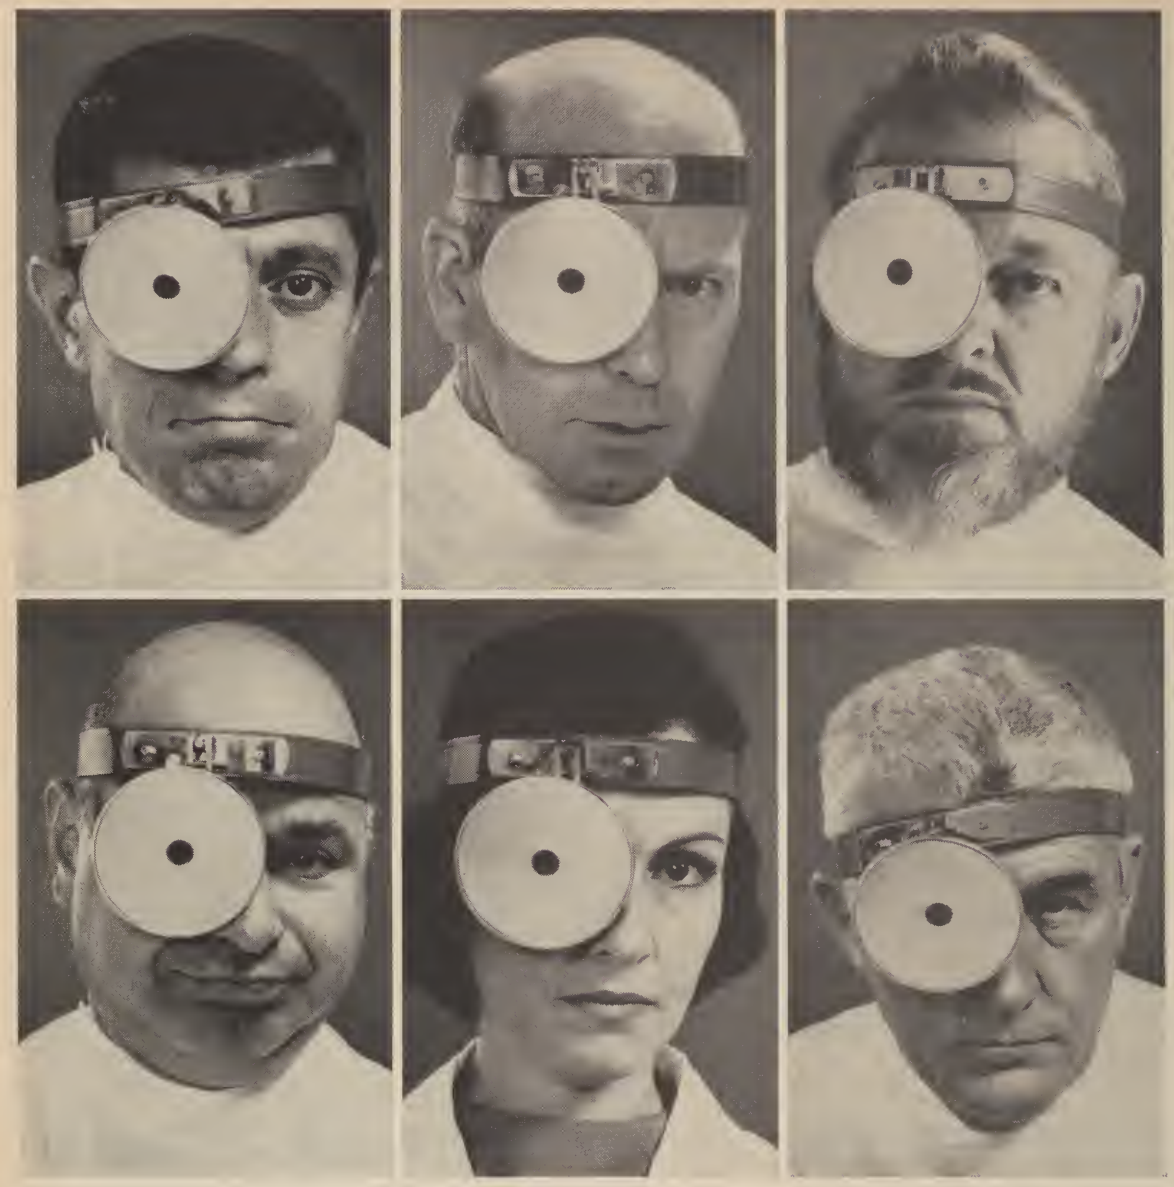
Long recognized for its usefulness in the treatment of moderate to severe anxiety, Mellaril is now also known to be effective against mixed anxiety-depression.

Often the symptoms of anxiety states are difficult to sort out—even with the most careful probing. The patient may manifest symptoms of agitation, restlessness, insomnia, somatic complaints. But what of the depression that may be mixed in the total picture? It is reassuring to know that Mellaril may be prescribed—with strong possibilities of success—when there is anxiety alone or a mixture of anxiety and depression.

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.



Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine hydrochloride). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

Mellaril®
(Thioridazine HCl)
25 mg. t.i.d.

for moderate to severe anxiety and mixed anxiety-depression

SANDOZ SANDOZ PHARMACEUTICALS, HANOVER, N. J. 68-170

"All Otolaryngologists are Alike"

Just look at them and you can see how much they have in common. Besides, they all go through pretty much the same training, and pass the same kinds of tests, and measure up to the same sort of standards. Therefore, all otolaryngologists are alike. Right?

Wrong! But that's no more preposterous than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more exacting. In fact, there are at least nine *specific differences* involving moisture content, purity, potency and speed of tablet disintegration, which make the manufacture of Bayer® Aspirin so different.

These Bayer standards result in significant product benefits, including gentleness to the stomach and product stability, that enable Bayer Aspirin tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that *all* aspirin tablets are alike, you can say, with confidence, that "it just isn't so."

You might also say that all otolaryngologists aren't alike, either.

Bibliographies

The library staff spends a good part of its time in literature search, and compilation of bibliographies. In order that all physicians may know what is currently being produced, each month we will list those bibliographies completed during the period since the last MSMJ appeared. Recently, bibliographies have been completed on the following subjects:

1. Acne
2. Birth control in foreign countries
3. Emergency room management
4. Fees
5. Mononucleosis, Infectious
6. Multiple sclerosis
7. Ozone—Toxicity
8. Pancreatic hormones—Physiologic effects
9. Pregnancy and diabetes
10. Silicosis
11. Thoracic cannulation

Copies of these bibliographies will be sent to any physician or library requesting them.

BRONCHIAL DISTRESS

mudrane®

Emphysema, Chronic Bronchitis and Asthma are relieved in fifteen minutes by the fast-disintegrating, uncoated Mudrane tablet.

Checkpoints:

DILATES THE BRONCHI
DRAINS THE MUCUS
SEDATES MILDLY
SUSTAINED ACTION
SUPERIOR TOLERANCE

Each tablet contains:

POTASSIUM IODIDE	195 mg.
AMINOPHYLLINE	130 mg.
PHENOBARBITAL, Caution: may be habit forming.	21 mg.
EPHEDRINE HCl	16 mg.

FEDERAL LAW PROHIBITS DISPENSING WITHOUT PRESCRIPTION

Precautions: Usual for aminophylline-ephedrine-phenobarbital. Iodides may cause nausea, long use may cause goiter. Discontinue if symptoms of iodism develop. Iodide contraindications: tuberculosis, pregnancy.

DOSAGE: One tablet, with full glass of water, 3 or 4 times daily.

Dispensed in bottles of 100 and 1000 tablets.

BRONCHIAL DISTRESS

To help avert chronicity in acute cystitis

Artist's rendition of E. coli. As with most strains of E. coli, these have flagella and are motile.

Although it may coexist wit chronic pyelonephritis or prosta titis, many cases of chronic cyst tis may result from incomplet treatment of a simple, acute cyst tis. For this reason, it is bein increasingly recommended tha appropriate antibacterial therap in full dosage be maintained fo up to two weeks or longer.

Most frequently, the dominan pathogen is gram-negative, usu ally *E. coli;* most often, you wil find Gantanol® (sulfamethox azole) effective against *E. co* and other sensitive organisms– gram-positive and gram-negativ —commonly seen in cystitis an other urinary tract infections Wide clinical usage of Gantanc has confirmed the efficacy of thi wide-spectrum antimicrobia agent in the treatment of cystitis

The rapidity of bacterial mul tiplication in a favorable urinar environment is well known Prompt control of acute bladde infection is therefore essentia

---

Before prescribing, please consult com plete product information, a summary o which follows:

Indications: Acute and chronic urinar tract, respiratory and soft tissue infec tions due to susceptible microorganisms prophylactically following diagnostic ir strumental procedures on genitourinar tract.

Contraindicated in sulfonamide-sensitiv patients, pregnant females at term, pre mature infants, or newborn infants dur ing first 3 months of life.

Warnings: Use only after critical ap praisal in patients with liver or rena damage, urinary obstruction or bloo dyscrasias. Deaths reported from hy persensitivity reactions, Stevens-Johnso syndrome, agranulocytosis, aplastic ane mia and other blood dyscrasias. In closely intermittent or prolonged therapy, bloo counts and liver and kidney function test should be performed. Clinical data insuf ficient on prolonged or recurrent therapy in chronic renal diseases of children un der 6 years.

Precautions: Occasional failures may oc cur due to resistant microorganisms. No effective in virus and rickettsial infec tions. Sulfonamides not recommende

not only to reduce the patient's discomfort but to prevent chronicity and possible ascending infection.

Gantanol (sulfamethoxazole) provides antibacterial activity within two hours of the initial 2-Gm dose, and subsequent 1-Gm doses, taken morning and evening, maintain therapeutic blood and urine levels lasting up to 12 hours. Significant symptomatic response is frequently achieved within 24 to 48 hours in acute, uncomplicated cystitis and other responsive urinary tract infections. In addition, Gantanol is usually well tolerated. Should prolonged therapy be required, the convenient *b.i.d.* dosage helps to minimize the problem of skipped doses.

Over eight years' clinical use has thoroughly demonstrated the qualities that make Gantanol a good choice for initial therapy of most urinary tract infections, including acute cystitis.

---

for therapy of acute infections caused by group A beta-hemolytic streptococci. At present, penicillin is drug of choice in acute group A beta-hemolytic streptococcal infections; although Gantanol has produced favorable bacteriologic conversion rates in this infection, data insufficient on long-term follow-up studies as to its effect on sequelae of rheumatic fever or acute glomerulonephritis. If other treatment cannot be used and Gantanol is employed in such infections, *important that therapy be continued in usual recommended dosage for at least 10 days.* Observe usual sulfonamide therapy precautions, including adequate fluid intake. Use with caution if history of allergies and/or asthma. Follow closely patients with renal impairment since this may cause excessive drug accumulation. Need for indicated local measures or surgery not obviated in localized infections.

Adverse Reactions: Depending upon the severity of the reaction, may withdraw drug in event of headache, nausea, vomiting, urticaria, diarrhea, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, Stevens-Johnson syndrome, skin rash, injection of the conjunctiva and sclera, petechiae, purpura, hematuria and crystalluria.

Gantanol®
(sulfamethoxazole)
assures rapid, sustained, antibacterial activity with b.i.d. dosage

Gantanol® B.I.D.
(sulfamethoxazole)

CANNIBALISM IN THE CURRICULUM?

Some years ago, a professor at the University of Michigan published the results of his experiments with planaria. Flatworms that had been trained to gather in groups when exposed to the light of a lamp were ground up into a broth that was then fed to untrained planaria. The remarkable outcome was that the untrained worms responded to the same stimulus in the same way.

Subsequent experiments by other investigators have shown that similar results, using brain and liver extracts, could be demonstrated in rats, mice and hamsters. Not only this, but it seems possible, by injecting an enzyme that destroys RNA (ribonucleic acid), to reduce the capacity of these animals to learn. The belief of many cannibal tribes that eating the flesh of their brave enemies transfers their courage to the ingester thus seems to receive scientific confirmation.

Unfortunately, many other experimenters have not been able to duplicate these results. The day when medical students can be aided in their understanding of the fantastic biochemistry of our brave new world by eating the ground-up brains or livers of their professors is still only a remote possibility. Isn't science wonderful!

Gastrointestinal Disorders are a Challenge to Insurance Underwriters

A panel of life insurance medical directors agreed recently that common diseases and disorders of man may be more significant than first realized and may offer some of the most challenging problems to the life insurance underwriter.

Impairments such as peptic ulcer, polyps, vertigo and hiatal hernia are often encountered, the panel agreed, and may develop, or be part of, a more serious condition leading to increased mortality. The panel presentation was part of the annual meeting of the Association of Life Insurance Medical Directors of America in St. Louis in October.

The frequency of a peptic ulcer in at least 12% of the population, a panel member said, emphasizes the possibility of complications that could lead to increased mortality.

He told the medical directors that underwriting problems most often occur in "differential diagnosis," and when a decision is made on incomplete or questionable information.

The industry is "very dependent" upon attending physicians when underwriting most gastrointestinal disorders, since the insurance examination provides few significant findings.

The Name

We have now completed our quadrennial balloting for national leadership. Physicians, no doubt, rank high in percentage of voters as compared to other occupational groups. The news media have brought into focus several ground swells in connection with this close election. Both conventions seemed to have lost personal involvement with the voter. Most recent figures show the total popular presidential vote to have been some five million less than that predicted. Some evidently feel the issues were not sharply defined enough by the parties. A vocal minority unsuccessfully attempted to disrupt the entire system. But even this attempt at disruption, this continual confusion by heckling, this negation of all candidates and their programs, this movement toward anarchy, even the nomination of a pig for president, if you will, represents, by its very opposition to the system, partial participation in it.

Nonparticipants

How many of us, disappointed with issue clarification and both candidates, did not participate in the voting? The number of physicians in this category will never be exactly known, and the figure is not important. For those who did not feel that a choice could be made and, therefore, cast no presidential vote, that is their right. But not to vote implies acceptance of the winner, whoever he might be. Thus, until the next election, these individuals should not complain of any national

of the Game

policy or direction unless prefaced by the fact that they were not participants, merely observers.

An analogous situation confronts the medical profession. The system has provided us with a leadership and policy-making organization, the American Medical Association. There is no lack of individual medical voices to be heard in criticism of this body. But how many of these voices are members of the AMA, much less active participants in its workings? Do they belong to local state and national societies? Do they attend their meetings? Do they accept hard-working committee memberships? Do they verbalize their complaints at organization meetings?

For those of us whose answer is "no" to the above questions, and who have great differences with the structure and policy of the AMA, the proper appellation is nonparticipant. We are less participatory than if we let our hair grow, stopped washing, picketed and disrupted meetings, and even nominated animals for high office.

The voluntary nonparticipant, then, should hold his tongue as firmly in regard to the AMA as to the national political scene. If the stimulus to speak out is strong enough, dissatisfaction acute enough, and commitment to ideas deep enough, then let him pay the admission price of vocal criticism: active membership in the organization. Nonparticipation implies acceptance.

The rules of the game are known as democracy. The name of the game is participation.

Fellowship Opportunities

Fellowship in Clinical Applications of Radioisotopes

The Division of Nuclear Medicine of the Stanford University Department of Radiology invites applications for a one-year or two-year fellowship in clinical applications of radioisotopes. The program includes training in isotope methodology and instrumentation as well as clinical and research experience and is designed for those with a special interest in nuclear medicine or oncology.

Openings are now available for July 1 and September 1, 1969. Applicants must have completed two years of postgraduate resident training. The salary is $9,000 a year.

Further information may be obtained from Joseph P. Kriss, MD, Professor of Medicine and Radiology, Nuclear Medicine Division, Stanford University Hospital, Stanford, California 94304.

Training Program in Gastroenterology

A clinical and research fellowship program in gastroenterology will be initiated on July 1, 1969, by the gastrointestinal and nutrition unit of the Department of Medicine of Montefiore Hospital (500-bed general hospital) and the University of Pittsburgh School of Medicine. The unit, which is staffed by five gastroenterologists, is under direction of a full-time faculty.

The fellowship will include care for the patients seen in the gastrointestinal clinic and consultations for the ward and private patients.

Further information may be obtained from Siamak A. Abidi, MD, PhD, Department of Medicine, Montefiore Hospital, Pittsburgh, Pennsylvania 15213.

No injection after all!

This penicillin produces high, fast levels—orally.

Pen•Vee® K is usually so rapidly and completely absorbed that therapeutic penicillin levels are attained within 15 to 30 minutes. Thus it can often obviate the need for penicillin injections. The higher serum levels produced generally last longer than with those of oral penicillin G.

Indications: Infections susceptible to oral penicillin G: prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.
Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.
Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.
Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.
Adverse Reactions: (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").
Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

ECG
and complete examination normal
(persistent palpitations)

Valium®
(diazepam)

for reliable relief of psychic tension and associated somatic and depressive symptoms (including tension-induced insomnia)... usually well tolerated... 2-mg, 5-mg or 10-mg tablets *t.i.d.* and *h.s.*

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms have occurred following abrupt discontinuance. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation, have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

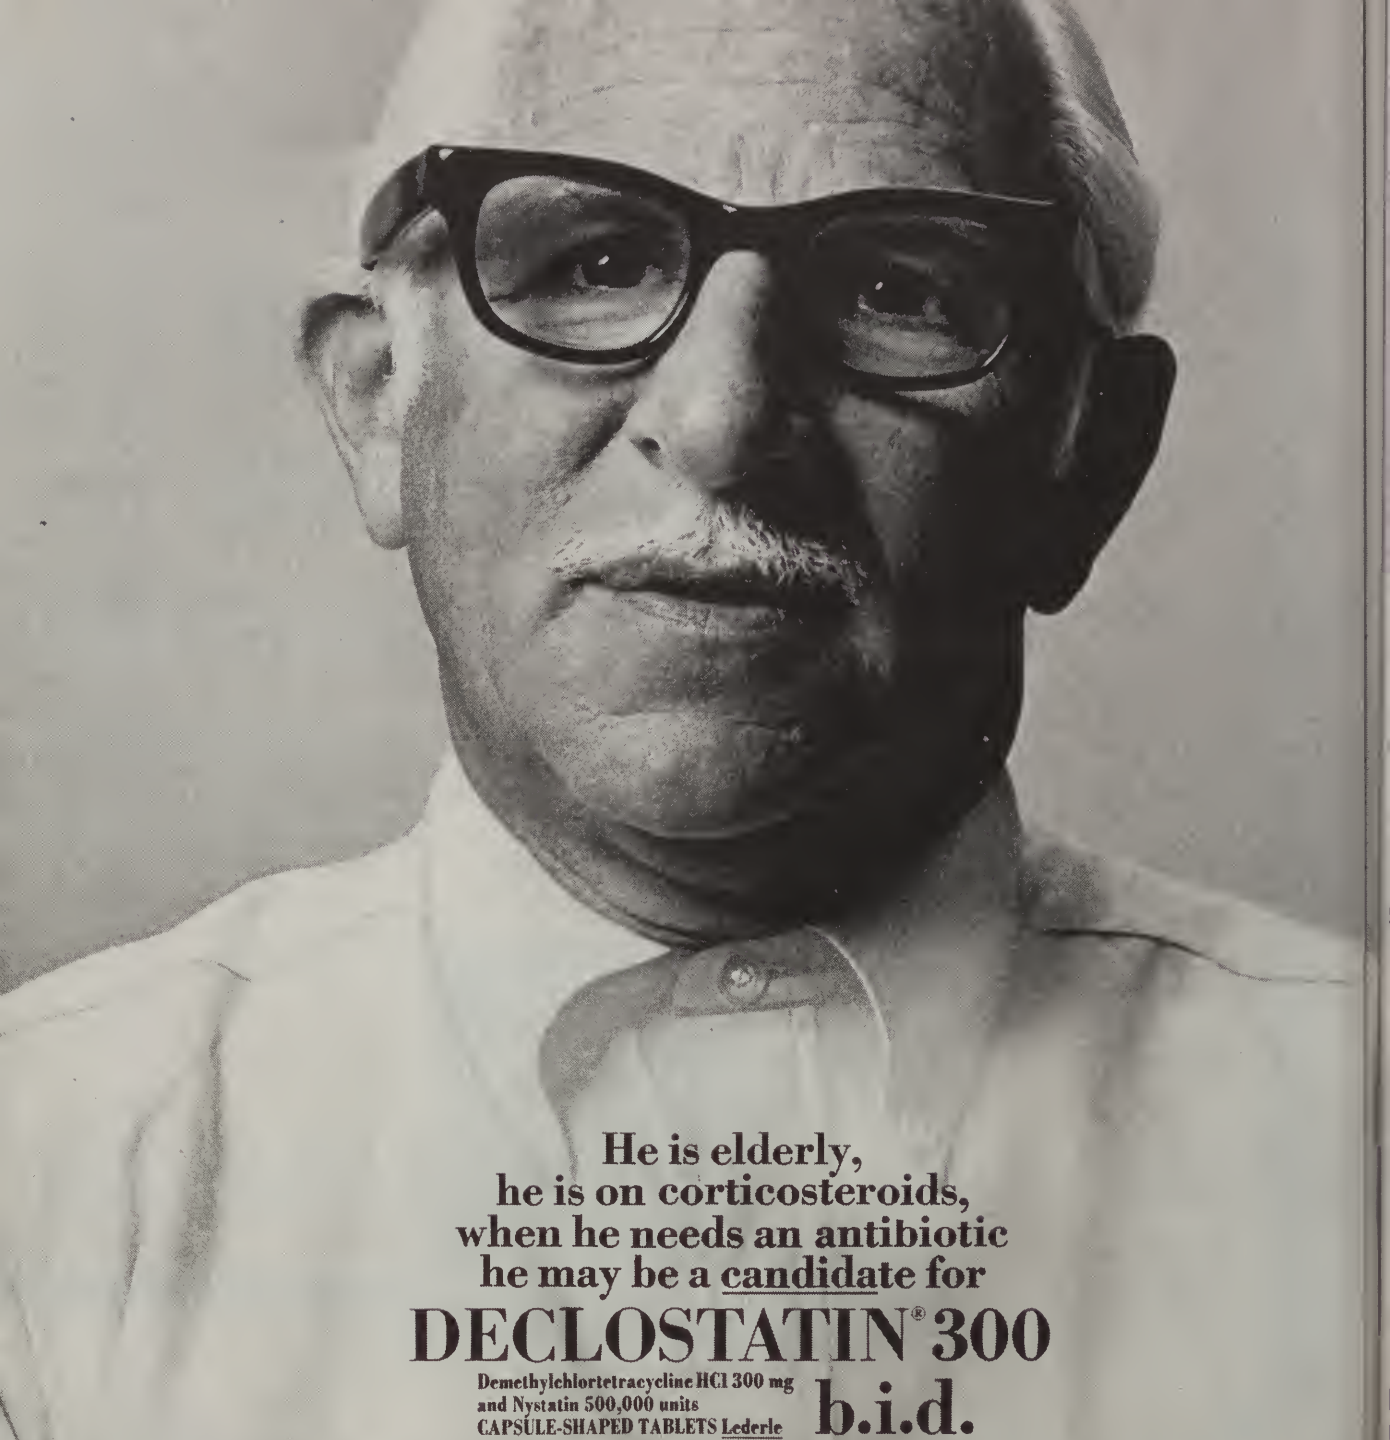
3000 UNIT TABLETS

IN THE TREATMENT OF FUNCTIONAL DYSMENORRHEA AND SELECTED CASES OF PREMATURE LABOR AND 2ND AND 3RD TRIMESTER THREATENED ABORTION

■ LUTREXIN, the non-steroid "uterine relaxing factor" has been found to be useful by many clinicians in controlling abnormal uterine activity.

■ Literature on indications and dosage available on request.

■ No side effects have been reported, even when massive doses (25 tablets per day) were administered.



■ Supplied in bottles of twenty-five 3,000 unit tablets.

(In vivo measurement of Lutrexin on contracting uterine muscle of the guinea pig.)

HYNSON, WESTCOTT & DUNNING, INC. BALTIMORE, MARYLAND 21201

(LTR23)

He is elderly, he is on corticosteroids, when he needs an antibiotic he may be a candidate for

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg and Nystatin 500,000 units CAPSULE-SHAPED TABLETS Lederle

b.i.d.

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, app measures should be taken.

In infants, increased intracranial pressure with bulging fonta been observed. All signs and symptoms have disappeared rapid cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomitir rhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—mac ular and erythematous rashes; a rare case of exfoliative dermat been reported. Photosensitivity; onycholysis and discoloration nails (rare). Kidney—rise in BUN, apparently dose related. T increase in urinary output, sometimes accompanied by thirst Hypersensitivity reactions—urticaria, angioneurotic edema, anap Teeth—dental staining (yellow-brown) in children of mothers gi drug during the latter half of pregnancy, and in children given t during the neonatal period, infancy and early childhood. Enam plasia has been seen in a few children. If adverse reaction or crasy occurs, discontinue medication and institute appropriate

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Sh given 1 hour before or 2 hours after meals, since absorption is i by the concomitant administration of high calcium content drug and some dairy products. Treatment of streptococcal infections continue for 10 days, even though symptoms have subsided.

VOLUME 18 MAY 1969 NUMBER 5

CONTENTS:

Editorial—What's In a Name? Jeanne B. Sargeant 59

Human Kidney Transplantation: Present Status and Projected Future, Bruce H. Stewart, MD, Ralph A. Straffon, MD 61
"Renal homotransplantation, although still developmental, has already proven to be an effective treatment for many patients dying of terminal renal failure. Patients receiving kidneys from living related donors can expect at least a 75% one-year survival rate; those receiving kidneys from non-living donors average about 50% one-year survival. . . ."

Renal Homotransplantation, Paul Bormel, MD 68
Although the transplantation of human organs appears to be a relatively recent innovation in the medical field, its concept dates back to the ancient mythology of Egypt, Greece, and Rome.

The Management of Behavior Disorders in the Geriatric Patient, John Spencer, MD 73
"Organic disease or dysfunction in the aged can often obscure the presence of mental or emotional disorder. The hostile or confused behavior of a geriatric patient who is hard of hearing, for example, is more likely to be attributed to his sensory deficiency than to underlying mental disorder."

Preliminary Report on the Dietary Management of Patients With Advanced Carcinoma, Barbara A. Solomon, MD, MA 77
"Frequently, the main problem concerning patients with terminal types of carcinoma is anorexia, nausea, and vomiting. In an attempt to counteract these symptoms, the resulting malnutrition, and weight loss in three cases of carcinoma, the following diet was devised."

Sarcoma Botryoides, H. Melvin Radman, MD 80
"Several years ago, unusual findings were reported in a patient with a huge abdominal mass. It was thought that the tumor was not associated with disease of the genital system, but rather represented an example of primary omental sarcoma. Most authorities would agree than an accurate clinical or pathological diagnosis is difficult in such an entity. Subsequent events proved the validity of this contention."

Postoperative Management of Infants, J. Alex Haller, MD 85
"As an area of special interest, pediatric surgery has developed primarily for two reasons, The first of these is the unique nature of congenital anomalies which occur in the newborn and which, if not recognized and immediately treated, will result in death of the baby, or a severely debilitated child. The second reason has been a gradual realization that the physiological responses of a baby are quantitatively and qualitatively different from an adult and that dramatic changes can occur with greater rapidity during the operative and postoperative care of an infant . . ."

ANNUAL MEETING REGISTRATION

The 1969 Annual Meeting recorded the highest registration ever for the annual session of the Faculty. Registration totalled 1508. The breakdown is as follows:

Physicians	815
Residents & Interns	65
Medical Students, Technicians, Nurses & Other Allied Health Persons	362
Exhibitors	266

BLUE SHIELD REPORT

Maryland Medical Service, Inc., Maryland's Blue Shield plan, reported at its annual session that benefits paid on behalf of its members include:

$20.6 million to help cover the cost of 643,600 physician's services
$10.8 million in Part B, Medical Care benefits to those over Age 65 (263,400 claims)
$2.5 million in CHAMPUS claims for some 12,000 individual benefits

Enrollment in Blue Shield increased to 1,097,000 persons at the end of 1968, the highest figure recorded. Some 1,270,500 persons are enrolled in Maryland Hospital Service, Inc., programs, Maryland's Blue Cross plan.

BLUE CROSS BOARD

Physician members of the Blue Cross Board are:

J. Tyler Baker, MD, Easton
William D. Lynn, MD, Baltimore
B. Martin Middleton, MD, Baltimore
J. Arthur Weinberg, MD, Baltimore
Richard A. Young, MD, Hagerstown

WORKMEN'S COMPENSATION CHARGES

The Faculty's House of Delegates at its Annual Session voted without dissent to adopt a resolution reaffirming its position with respect to payment of Usual, Customary and Reasonable Fees.

In doing so, the Faculty takes the position that the law provides for payment on this basis; and is willing

WORKMEN'S COMPENSATION CHARGES (cont'd)

to take the issue to court, if necessary.

Insurance carriers repeatedly state they are bound not to exceed the current fee guide promulgated by the Workmen's Compensation Commission in 1961. The Commission Chairman has stated otherwise. However individual Commissioners, when cases have come before them for arbitration, state the guide listing prevails.

The important points in the resolution adopted include

"....there is no reason for medical services rendered to Workmen's Compensation recipients to be compensated for at fees differing from those received for such services rendered to other patients."

and

"....that physicians in Maryland be urged to advise all insurance carriers that they intend to charge Usual Customary and Reasonable fees for...(such) cases seen by them....that physicians who elect not to see such...cases because of this arbitrary attitude...should notify the insurance carriers requesting them to seek the services of other physicians for care of such patients."

TRIP TO SPAIN

The Faculty is planning a jet-charter trip to Spain, October 12 through 21, 1969. Interested persons should contact Mrs. Beverly Wolins, Travel Guide Agency, 416 N. Charles Street, Baltimore, Md. 210 Telephone 727-0682.

1969/70 MEMBERSHIP DIRECTORY

Reply cards with membership listings for the 1969/0 membership directory will be in the mail in the next few weeks. Be on the lookout for them and indicate any changes necessary before returning them to us for printing.

PRESIDENTIAL

Be on the lookout, also, for a communication from the Faculty President.

This four-page letter contains important information regarding the Commission on Medical Discipline as well as other data of current interest and concern.

Baltimore City Medical Society

MEETING NOTES

The January 14, 1969 meeting of the Board of Directors was called to order by the President, Raymond C. V. Robinson, MD, at 4:30 P.M. Ten members of the Board were present.

The minutes of the December 3, 1968 meeting were approved as written.

Four members of the Society were proposed for Emeritus Membership. These include: Jacob R. Jensen, MD, an associate member of the Baltimore City Medical Society since 1953; Leo Kanner, MD, an active member since 1939; S. Demarco, MD, an active member since 1942; and C. W. Peake, MD, an active member since 1942. All of these physicians have retired from practicing medicine.

Morris B. Levin, MD, appeared before the Board on behalf of two resolutions he had presented at the December 6, 1968 meeting of the Society. These resolutions and two others presented by the Policy and Planning Committee were considered by the Board. The resolutions and the Board recommendations are as follows:

RESOLUTION I-69

PRESENTED BY: The Policy and Planning Committee, Chairman, Philip F. Wagley, MD

RESOLVED, That the Bylaws Committee be directed to draft and present to the Society an amendment to the Bylaws providing that before admission to membership, an applicant attend at least two orientation meetings where he would be informed as to the roles of the Society in the community life and assess what particular interests he might have in those roles.

RECOMMENDATION OF THE BOARD OF DIRECTORS

The Board of Directors agrees wholeheartedly with the intent of this resolution. It was suggested by the Board and agreed to by the Chairman of the Policy and Planning Committee that one orientation meeting would be sufficient to attain the goals set forth in the resolution. The resolution has been amended accordingly and is submitted for adoption as shown below.

If this resolution is passed by the Society, the Board of Directors suggests that an expanded Membership Committee be charged with meeting with the applicants for membership prior to their election to implement this resolution.

AMENDED RESOLUTION I-69

RESOLVED, That the Bylaws Committee be directed to draft and present to the Society an amendment to the Bylaws providing that before admission to membership, an applicant attend at least *one orientation meeting* where he would be informed as to the roles of the Society in the community life and assess what particular interests he might have in those roles.

The Board of Directors recommends adoption of this resolution in the amended form.

RESOLUTION II-69

PRESENTED BY: The Policy and Planning Committee, Chairman, Philip F. Wagley, MD

RESOLVED, That the Society refer to the Policy and Planning Committee the continuing study of socio-economic problems, including the feasibility of setting aside funds for use to defray a significant amount of the cost of pre-medical and medical education for some young student in the inner city.

RECOMMENDATION OF THE BOARD OF DIRECTORS

The Board of Directors recommends adoption of this resolution which charges the Policy and Planning Committee with further study as outlined.

RESOLUTION III-69

PRESENTED BY: Morris B. Levin, MD

WHEREAS, The members of the State Board of Medical Examiners are supposedly voted on by all physicians licensed to practice in the State and in good standing, whether members of societies or not; and

WHEREAS, Each licensed physician throughout the State, in good standing, is entitled to his vote by secret ballot by mail; but, at present many are deprived from doing so; and

WHEREAS, Otherwise, the individual State Society member cannot exercise the inherent right to his direct vote because this right has been usurped by the House of Delegates, which even qualifies submission of resolutions; and

WHEREAS, Our House of Delegates may represent a majority, but not the views of the entire medical profession in the State, be it therefore,

RESOLVED, That the Baltimore City Medical Society direct its delegates to the State Society, to so correct the state and component society bylaws, as to return to each member of the state and component societies, his inherent irrevocable right to vote by secret ballot by mail, for all officers and all matters of importance involving the welfare and existence of the societies, the profession and the public; and, be it further

RESOLVED, That if the Medical and Chirurgical Faculty by its bylaws is unwilling to encompass all physicians in good standing in the State, to vote by secret ballot for members of the State Board of Medical Examiners and other matters of importance to the public; then have the membership petition the legislature to charter a Maryland Physicians' Society, wherein each member shall have the irrevocable inherent right to vote by secret ballot by mail and thereby speak as the voice of the entire State medical profession.

RECOMMENDATION OF THE BOARD OF DIRECTORS

For the reasons listed below, the Board of Directors feels that this resolution should not be adopted.

The Annotated Code of Maryland (Article 43, Section 120) provides that the members of the Board of Medical Examiners be elected by the Medical and Chirurgical Faculty at its Annual Meeting.

The House of Delegates of the Medical and Chirurgical Faculty is composed of members elected by the component societies as their representatives and, therefore, is representative of the membership of the Medical and Chirurgical Faculty.

The Board of Medical Examiners is not elected by the House of Delegates, but by the entire membership of the Medical and Chirurgical Faculty at a general meeting held during the Annual Meeting of the Medical and Chirurgical Faculty.

RESOLUTION IV-69

PRESENTED BY: Morris B. Levin, MD

WHEREAS, Two branches of our State Government are planning comprehensive corrective measures to improve health care to the public; and,

WHEREAS, These branches are trying to halt the ascent of hospital and other health costs; and,

WHEREAS, Hospital administrators claim the greatest rise of hospital costs is due to the public service of their personnel; and,

WHEREAS, These hospitals which can no longer exist without public tax support, restrict the use of their beds and facilities to a small minority of physicians chosen behind closed doors by arbitrary standards; and,

WHEREAS, The denial of the use of hospital beds and facilities by the hospital examining boards to the majority of all physicians in good standing in the community, is a serious discrimination opposed to the public and professional interest and welfare; and, blocks the enhancement of the quality of medical care to the public; and further,

WHEREAS, The finest services to the patient, can be rendered only by his personal doctor; be it therefore,

RESOLVED, That the Baltimore City Medical Society direct its State Society delegates, to petition the legislative and executive branches of our State Government to require uniform examinations and qualifications for all practicing physicians everywhere in the State, whether inside or outside hospitals; and, be it

RESOLVED, That the State Board of Medical Examiners be the sole examining and qualifying Board for this purpose; and if necessary, be so constituted as to certify all specialists and general practicing physicians alike; and, to utilize hospital assistance if necessary for uniformity; and, be it

RESOLVED, That among our profession, privileged individuals or groups be abolished; and, discrimination be based solely on professional qualifications and professional conduct; and, further be it

RESOLVED, That any hospital or other medical institution receiving any tax support and yet discriminating against any person and his physician, by denying the use of its beds and facilities to any doctor on any basis other than such uniform professional qualifications and conduct, shall be denied such tax support or subsidy.

RECOMMENDATION OF THE BOARD OF DIRECTORS

The Board of Directors recommends that this resolution not be adopted.

According to the laws of Maryland, each hospital sets up criteria for election to its professional staff of qualified physicians. The Baltimore City Medical Society and the Medical and Chirurgical Faculty have no control over the individual hospital. In at least two court trials the right of the hospital staff to select its own members has been upheld. One of these decisions declared "The hospital's receipt of public funds and its exemption from taxation did not transfer it into a public hospital, the court said. Since the hospital was a private institution, it had the right to refuse to reappoint the physician to its medical staff." (Quoted from The Citation, Vol. 14, No. 7, p. 107.)

COMMENTS

The Board of Directors has appointed a committee to study several facets of hospital utilization. Some of the problems which will be considered are physicians who want multiple privileges, physicians who want no hospital privileges, physicians who lack proper qualifications for admission to hospital staffs, and the effect of expanded staffs on the accreditation of resident training programs.

The next item under discussion was the selection of a date for the semiannual meeting of the Society. It was agreed that since the first Friday in April is a holiday, the Semiannual Business Meeting will be held on Friday, March 28, 1969.

The annual report of the Liaison Committee between the Hospitals of Baltimore and the Baltimore City Medical Society was discussed. Dr. Robinson suggested and the Board concurred that Samuel Morrison, MD, be asked to remain as chairman of this Committee for the coming year.

The next item on the agenda was the discussion of a letter to be sent to Mayor D'Alesandro regarding the reappointment of Robert E. Farber, MD, as Commissioner of Health for Baltimore city. The Board agreed that Dr. Farber's performance as Commissioner of the Health Department of Baltimore City was one of excellence, and strongly recommended his reappointment.

In response to a request, the Board agreed to give the Med-Chi Subcommittee on Narcotic Prescribing Practices the authority to investigate the prescribing practices of several Baltimore city physicians.

The meeting was adjourned at 6:30 P.M.

The minutes of the February meeting were recorded in the April issue of the JOURNAL.

March Minutes

The Board of Directors of the Baltimore City Medical Society met at 1211 Cathedral Street on March 11, 1969 at 4:30 P.M. The meeting was called to order by Raymond C. V. Robinson, MD.

The minutes of the February 11th meeting were approved.

A lengthly report was submitted from the Health and Welfare Council describing its operation and services. This report was referred to John Classen, MD, for review requesting that a synopsis be prepared and presented to the Board at the next meeting.

The next item on the agenda was the discussion of a letter from Villa Julie College soliciting financial support from the Baltimore City Medical Society. The Board was of the opinion that the hiring of the graduates of this program was in itself supportive and felt that it could not render direct financial assistance to this training program. The Board suggested to the College that perhaps the matter should be considered by the Medical and Chirurgical Faculty.

The Board agreed to waive the dues of Isaac Miller, MD who is unable to practice medicine due to illness.

The next item on the agenda reviewed the purpose of the Baltimore City Medical Society Legislative Committee. It was agreed by the Board that Howard Moses, MD, Legislative Committee Chairman and representative to the State Legislative Committee, should be requested to report to the Board of Directors at any time he feels the Board should be informed of the Committee's activities or when action by the Board is deemed desirable. It was felt, however, that the previous suggestion by the Committee should not be cultivated and the Baltimore City Medical Society should not develop the habit of entertaining local legislators in an attempt to facilitate rapport.

A letter had been received from the Baltimore City Health Department concerning a member of the Society presently under investigation by the Health Department for maintaining a poor facility and housekeeping practices in offices offering medical services. The letter suggested that the Society investigate this matter, however, the Board decided that this specific case was to be turned

over to the Med-Chi Mediation Committee for its consideration and action.

Emmanuel Schimunek, MD informed the Board of the present state of financial investments of the Baltimore City Medical Society. He informed the Board of monies now held by the Society in bank accounts and suggested that some of this be used to purchase stock. After some discussion, it was agreed by the Board that a Society member and recognized financial expert be solicited for his suggestions and advice concerning future investment policies of the Society.

Dr. Robinson read a list of members who have been suspended from the Society for nonpayment of dues. Included in this list are seven active members and twelve associate members of the Baltimore City Medical Society.

The report of the Med-Chi Bylaws Committee as printed in the House of Delegates agenda was discussed. The proposal is to amend the Bylaws to read that the membership on the Med-Chi Council be selected according to the number of active and forty-year members in each district. This would result in the appointment of one representative from each district plus an additional representative for each two hundred active and forty-year members. This recommendation generated much discussion by the Board because the present Bylaw guarantees the Baltimore City Medical Society at least eight Councilors. The proposed amendment eliminates this guarantee so that all of the members from the Central District which includes Baltimore City, Baltimore and Harford counties, could be elected from either Baltimore or Harford county. After some discussion as to the manner in which this amendment could be altered, it was agreed that Dr. Robinson would send a letter to the entire membership informing them of the proposal and asking that they attend the next meeting of the Baltimore City Medical Society to express their views on this important issue. It was suggested that this letter emphasize that the largest segment of the membership in Med-Chi would not be guaranteed representation by the amendment as it now stands.

The next item on the agenda was the billing for laboratory tests. This item again created an enthusiastic response from the Board of Directors. The present policy for the billing of laboratory tests establishes that it is ethical for a physician to charge a fee for drawing blood but he cannot include the cost of the laboratory work in his bill unless the work is done in his office. On the other hand, Blue Shield has established a policy in which it will not pay for charges made by a physician for the drawing of blood and will only pay for the laboratory work performed. It was suggested that the Board of Directors of the Baltimore City Medical Society write the Society of Internal Medicine asking its views on this subject.

Dr. Robinson read several pieces of correspondence he had exchanged with the Med-Chi concerning the activities of the Narcotic Prescribing Practices Subcommittee of the Mediation Committee. Robert B. Goldstein, MD, who is a member of the Mediation Committee, explained that the Committee is now in the process of setting guidelines for the treatment of narcotic addicts to be adopted as policy by Med-Chi. These guidelines will be presented in the near future.

The Board was informed by the Woman's Auxiliary of the Baltimore City Medical Society that its members will serve refreshments at the monthly meetings of the Society.

The Board received a letter from Calbert T. Seebert, MD, Chairman of the Joint Anesthesia Study Committee requesting that funds be set aside by the Society to be used by this Committee to obtain out-of-town speakers. The Board agreed to write to Dr. Seebert expressing its cognizance of the important function served by this Committee and strongly supporting its continued effort. However, the present budgetary status of the Baltimore City Medical Society will not allow the funding as requested. It was suggested that Dr. Seebert contact pharmaceutical companies which market anesthesia supplies and request their financial aid for such a program.

Edward F. Cotter, MD, who is Chairman of the Committee to Study Hospital Privileges reported that this Committee had formulated a questionnaire which will be mailed to the membership asking information concerning their hospital privileges. Several suggestions were made concerning the wording and information to be gleaned from such a questionnaire by the Board of Directors. The questionnaire was then returned for further refinement prior to its next presentation to the Board.

A suggested amendment to the Baltimore City Medical Society Bylaws proposing that the slate of nominations be sent to the membership fifteen days before the presentation at the November meeting was discussed. Presently, the Bylaws require that the slate be sent out thirty days prior to the meeting which necessitates including the

slate in the mailing of the October bulletin. The Board agreed to request to the Bylaws Committee to prepare an appropriate amendment to the Bylaws.

The meeting was adjourned at 6:15 P.M.

Baltimore County Medical Association

Wilmer K. Gallagher, Jr., MD, president of the staff at St. Agnes Hospital, extended a cordial invitation to the members of the Baltimore County Medical Association to hold the March meeting at the Hospital. Following a delicious buffet luncheon, a very interesting scientific program was presented. The subject was "Medical Versus Surgical Concepts in the Treatment of Hyperthyroidism." The speakers were Luis Martin, MD, endocrinologist at the University of Maryland, and James Cianos, MD, a surgeon on the staff at St. Agnes. This is certainly a very controversial subject and was well received by our members. Our sincere thanks to the participants.

The following were elected to active membership: Joseph Cordi, MD, Theodore Toulan, MD, and Robert Yim, MD. The following physicians, all residents at the Sheppard and Enoch Pratt Hospital, were elected to associate membership: Cynthia Dulay, MD, Robert Duvall, MD, Ronald Goldberg, MD, Seana Herchfeld, MD, Kay Koller, MD, Harold Levin, MD, Apoltolos Pappas, MD, Betty Robinson, MD, Gerardo Rubenstein, MD, and Luciana Santiago, MD.

Our April meeting will be held at the Sheppard and Enoch Pratt Hospital and also in April our Association is holding a Dinner-Dance at the Tail of the Fox in Timonium.

Our Annual Crab Feast will be in August.

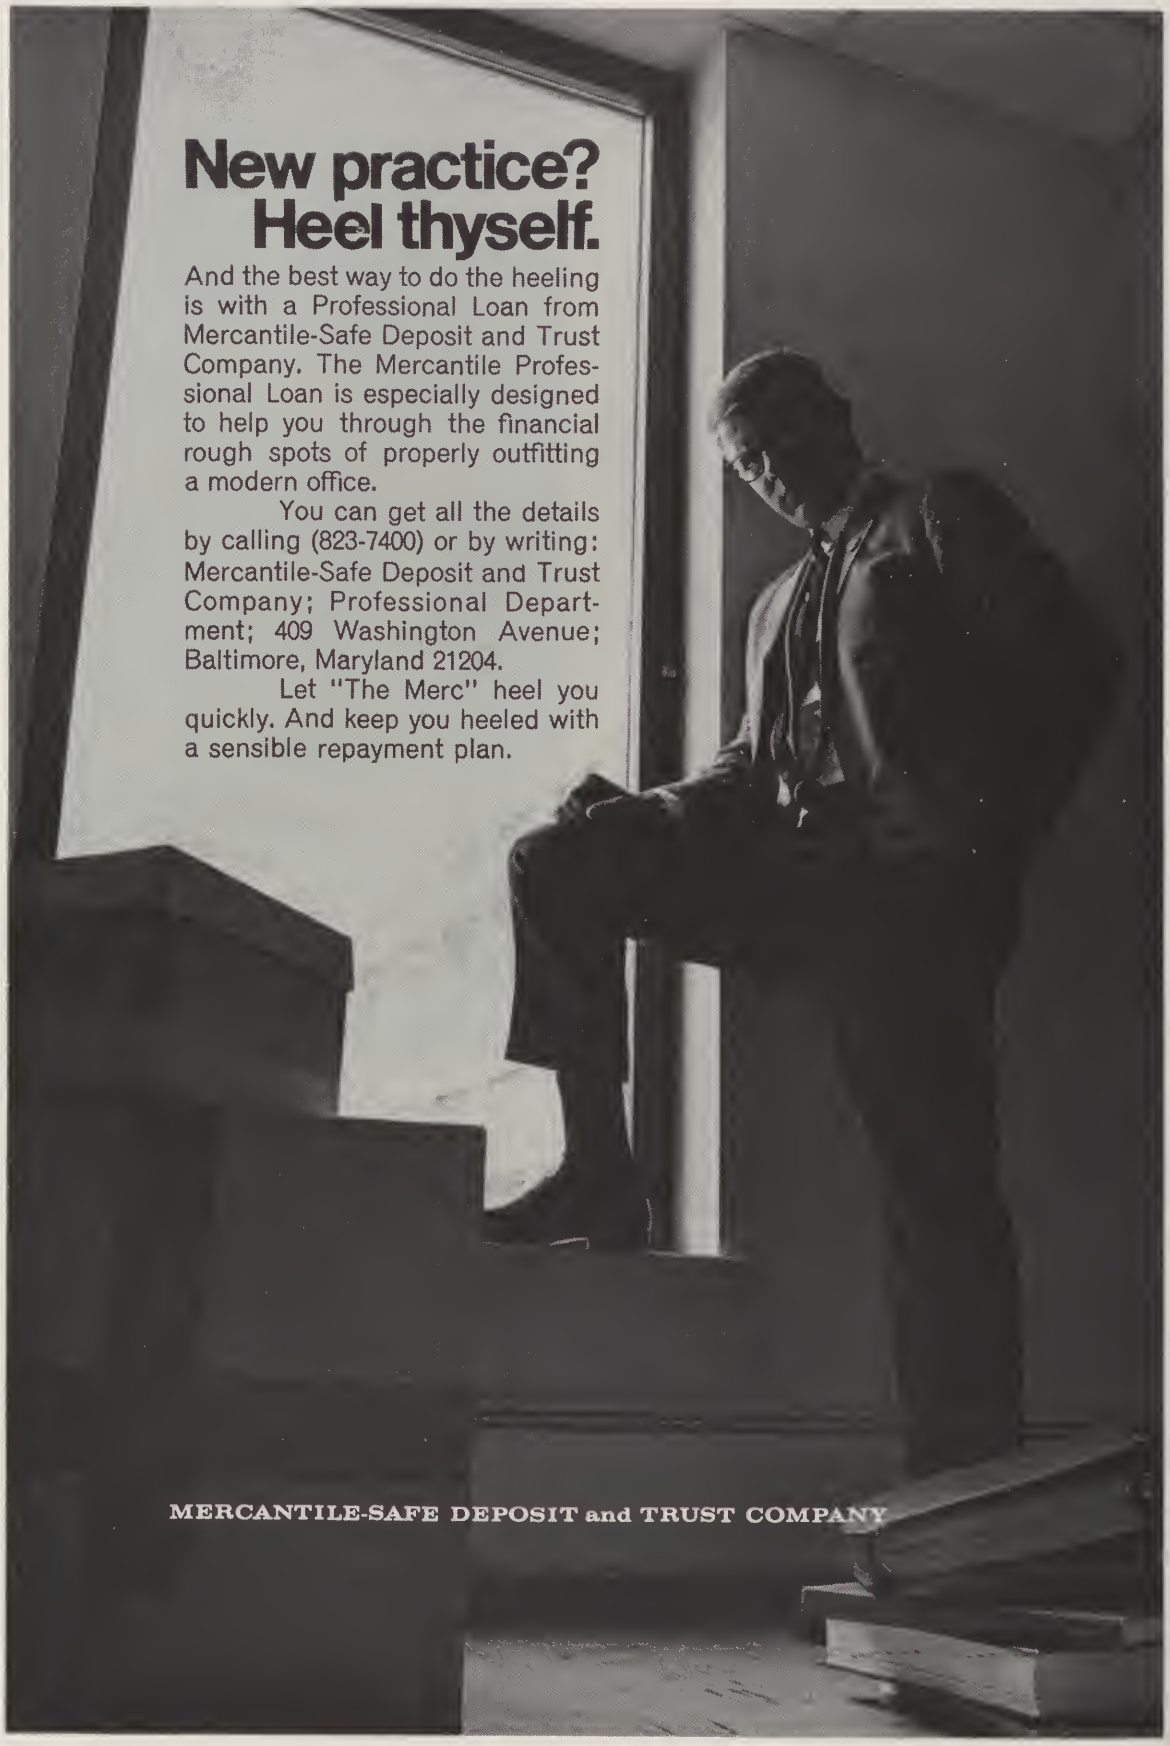
THE BETTMANN ARCHIVE



Just one tablet at bedtime • Prevents painful night leg cramps • Permits restful sleep

How many of your patients stamp their feet at night and lose sleep because of painful leg cramps? Unless prompted, they usually fail to report this distressing condition and suffer needlessly.

One tablet of QUINAMM at bedtime usually controls distressing night cramps and permits restful sleep with the initial dose.

Prescribing information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Side Effects/Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

THE MONTH IN WASHINGTON

The Department of Health, Education and Welfare has issued proposed regulations setting standards for rubella vaccine, making it possible for it to be ready for distribution in limited quantities by about June 1.

The standards cover production methods, safety, purity, and potency. They were developed by the Division of Biologics Standards, a unit of the National Institutes of Health. Final regulations could be published as early as May 3. Indications were that two manufacturers would have a vaccine ready for initial distribution soon after the regulations had been made final.

"This means that we are one step closer to the prevention of a disease that has caused an untold number of tragic births," HEW Secretary Robert H. Finch stated when the proposed regulations were issued.

"We are moving ahead to combat German measles in the quickest manner consistent with public safety."

The regulations apply to vaccines containing a live virus strain known as HPV-77, which is grown in either duck embryo or dog kidney cell culture systems. Experimental vaccines produced in accordance with the standards have undergone extensive community testing in the United States and abroad. Two manufacturers, Merck, Sharpe & Dohme and Philips Roxane Laboratories, have produced vaccines based on this strain.

"We hope that more than one vaccine will be available," Robert Q. Marston, MD, NIH Director, said. "Regulations covering the use of other virus strains and culture media for rubella vaccine production will be formulated on the basis of extensive tests now going on."

Smith Kline & French Laboratories has tested widely an experimental vaccine containing the Cendehill strain of rubella virus.

An HEW announcement stated:

"German measles is a threat to susceptible pregnant women any time, but the threat increases significantly during epidemic years. One of the most tragic and disastrous epidemics to hit the United States in modern times was the German measles epidemic of 1964-1965. This resulted in about 50,000 abnormal pregnancies. About 20,000 infants were born with such crippling defects as mental retardation, heart disease, blindness and deafness. The remaining 30,000 pregnancies terminated in miscarriage or stillbirth.

* * *

The Food and Drug Administration has taken the first step to halt the marketing of 78 antibiotic combination products.

The ultimate action was recommended by the National Academy of Sciences-National Research Council, which is evaluating the effectiveness of about 3,600 new drugs marketed from 1938 to 1962.

Generally, the 78 products were found ineffective as fixed combinations for claims made in their labeling. The FDA emphasized that this does not necessarily mean that either the antibiotics or other active ingredients of the products are ineffective when used alone.

"But the use of two or more active ingredients in the treatment of a patient who can be cured by one is irrational therapy," said Herbert L. Ley, Jr., MD, Commissioner of Food and Drugs. "It exposes the patient to an unnecessary risk. Antibiotics should be used like a rifle rather than a shotgun."

The majority of the 78 products are antibiotic-sulfa combinations in tablet, capsule, or liquid form. Also included are 16 penicillin-streptomycin combinations that are given by injection.

Other antibiotics used in the preparations include erythromycin, neomycin, tetracycline, chlortetracycline, nystatin, oxytetracycline, oleoandomycin, and triacetyloleandomycin. In addition, some of the preparations contain analgesics, vitamins, or other ingredients.

The antibiotics combinations are the products of 21 different manufacturers, including Chas. Pfizer & Co.; Eli Lilly & Co.; Lederle Laboratories, division of American Cyanamid Co.; Bristol Laboratories, Inc., a division of Bristol-Myers Co.; Merck & Co.; E. R. Squibb &

Sons Inc., a subsidiary of Squibb Beech-Nut Inc.; Upjohn Co.; Wyeth Laboratories Inc., a subsidiary of American Home Products Corp.; Abbott Laboratories; and Hoffman-La Roche Inc. In an earlier proposal last December, the FDA similarly moved against products marketed by Squibb, Lederle and Upjohn.

Many of the affected products have been promoted widely and have found wide acceptance in the medical profession. Several of the manufacturers promptly said they would contest the FDA ruling and others were expected to oppose it also. The manufacturers were given 30 days to submit any new data on efficacy of the products.

There were 12 products in the first groups, announced last December. A decision still was pending on whether manufacturers of those products should have additional time to submit evidence of efficacy.

The FDA can halt the marketing of antibiotic-containing preparations by deleting them from regulations listing the antibiotic drugs acceptable for certification. Antibiotics and insulin, unlike other drugs, must be certified on a batch-by-batch basis before they can be marketed.

* * *

Two spokesmen for the medical profession asserted before a Senate subcommittee that the policies and scientific journals of their organizations are not biased in favor of the prescription drug industry because of the drug advertising revenue.

Sen. Gaylord Nelson (D., Wis.), chairman of the Senate Monopoly Subcommittee which is making a broad study of the ethical drug industry, accused the medical journals of following the pharmaceutical industry's line to get advertising dollars.

Both Edward R. Annis, MD, a member of the AMA Board of Trustees, and Maynard I. Shapiro, MD, president of the AAGP, emphatically denied the charge. Both cited the high, objective advertising standards of their organizations' publications.

"The American Medical Association's programs and policies have never been, are not now, and will never be shaped by any dependence on the drug industry," Dr. Annis said. "And to assure that there is no conflict of interest, the AMA has consistently separated the editorial management, advertising acceptance, and business management of each of its scientific publications. . . .

"We believe that no publication surpasses our own standards for acceptable advertising."

Nelson sharply criticized the *Journal of the American Medical Association* as to the ads it carried on chloromycetin after the drug had been judged to be extremely dangerous. Annis acknowledged that "one Madison Avenue effort . . . slipped through the net" of AMA advertising standards. But he pointed out the various warnings on the drug which were carried in the editorial section of *JAMA* and other AMA publications.

"Advertising is screened by a group of physicians, all of whom we consider qualified to perform their task," Dr. Shapiro explained. "We don't list the names of these physicians in our magazines because we believe they prefer a degree of anonymity. All are medical school faculty members and all, in our opinion, are well qualified to screen pharmaceutical advertising."

Dr. Shapiro also said that at least two drugs firms had canceled ads in AAGP publications after they had carried editorials adverse to the companies.

* * *

The Nixon Administration recommended to Congress that the Hill-Burton hospital construction and improvement program be changed to permit block allocation of grant funds to states.

Since enactment of the first Hill-Burton legislation in 1946, federal grants for it have been earmarked for specific purposes.

In a statement to the House Health Subcommittee, Robert H. Finch, secretary of Health, Education and Welfare, said the nation's health needs had changed since the Hill-Burton program was started.

Today's needs, he said, are two-fold:

● Modernization or replacement of existing and obsolete acute care facilities in the hospitals and ● Expansion of other kinds of medical facilities to reduce the pressures on hospitals and help curb skyrocketing medical costs.

He recommended a $150 million annual grant authorization for construction, replacement or modernization of the most critical types of health facilities.

"Additionally, we recommend the removal of the existing Hill-Burton categories to

provide a better balance of health care facilities in the community by assisting those kinds of facilities which traditionally have been neglected or in short supply," he said.

Expansion of neighborhood health center programs also was recommended. The HEW statement said it was required to meet the health needs of the poor.

H. Phillip Hampton, MD, Tampa, Fla., testifying for the AMA, said the AMA continues its long-standing support of the Hill-Burton program but believes that "the major need that exists today is for the improvement and effective use of existing facilities."

"Priority for modernization and the upgrading of existing facilities will lessen the strain on the available supply of health personnel needed to provide services obtained in hospitals and related facilities," he said.

The AMA supported a provision in one of the two Hill-Burton bills before the subcommittee that would permit states to transfer funds from one allocation to another, providing "further elasticity to the transfer of funds from construction to modernization."

The AMA opposed, as unnecessary, the establishment of Hill-Burton priorities for construction or modernization of outpatient facilities or facilities to provide comprehensive health care. Such needs should be met through other laws already enacted, the AMA said. Dr. Hampton explained:

"We hope to make this point clear: We understand the part played by hospital outpatient departments in providing a place for necessary services to a community, and to the role played in teaching and training. But we believe that any need for outpatient facilities, separate and apart from the hospital, or for free-standing diagnostic and treatment centers—or whatever they may be called—can be met through other programs which provide Federal assistance. The Hill-Burton program is not the appropriate vehicle for grants or priorities for such separated facilities. Nothing has been demonstrated which indicates either public benefit or public acceptance for this concept of providing ambulatory medical care through hospital operated, rather than physician operated, neighborhood clinics."

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOS

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg.,
phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety...helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Amb suppresses appetite and helps offset em tional reactions to dieting. **Contraindic tions:** Hypersensitivity to barbiturates sympathomimetics; patients with advanc renal or hepatic disease. **Precautions:** Administer with ca tion in the presence of cardiovascular disease or hypertensio **Side Effects:** Nervousness or excitement occasionally not but usually infrequent at recommended dosages. Slight dro iness has been reported rarely. See package insert for furth details.

1969 Semiannual Meeting of the Medical and Chirurgical Faculty of Maryland

A meeting of interest and fun for all physicians, their wives, and families is being planned. In addition to the business and scientific sessions there will be several social events, a tour of the Amish Country for the ladies, and a tour of the new Hershey Medical Center of the Pennsylvania State University for the physicians.

More about the program will be published in the June issue of the Journal and the complete program will be mailed to all members of the Faculty early in August.

Complete and mail the following reservation form NOW.

SEE YOU IN HERSHEY!

Letters to the Editor

Dear Editor:

A commentary is necessary on the Ethics Corner Comment (January issue) with regard to the use of credit cards. Many physicians have been confused about the availability of the use of these credit cards, and your explanation is very timely.

However, attention must be directed to the fact that the entire economy of these United States is now based on credit. The fact that many of us were reared on a pay-as-you-go plan, does not gainsay the fact of present day existence which is nearly a total credit economy. In some respects we do ourselves a great disservice in not recognizing the changing times and making changes that are sensible and in the public interest, prior to the time that they are rammed down our throats.

Cases in point, of course, are the Medicare-Medicaid programs, which are with us and will be progressively managed by either ourselves or the federal and state governments. A similar situation exists with the use of credit and our failure to become modern enough to realistically cope with a situation which is upon us and will not change. The average person budgets practically their entire life against a credit system and completely runs afoul of his thinking when faced with medical bills. One fails to understand the reticence which is evident in this failure to use the credit card system. In fact, an agonizing reappraisal with some younger minds appears much in order immediately to make a determination of whether or not we are hastening our own downfall by failure to face the facts and endorse a socio-economic fait accompli.

For one, I believe that we should endorse, activate and supervise credit card systems related to our medical practice and take ourselves to the greatest extent possible out of the bill collecting and finance business.

Sincerely,

ROSS Z. PIERPONT, MD
Baltimore

Dear Editor:

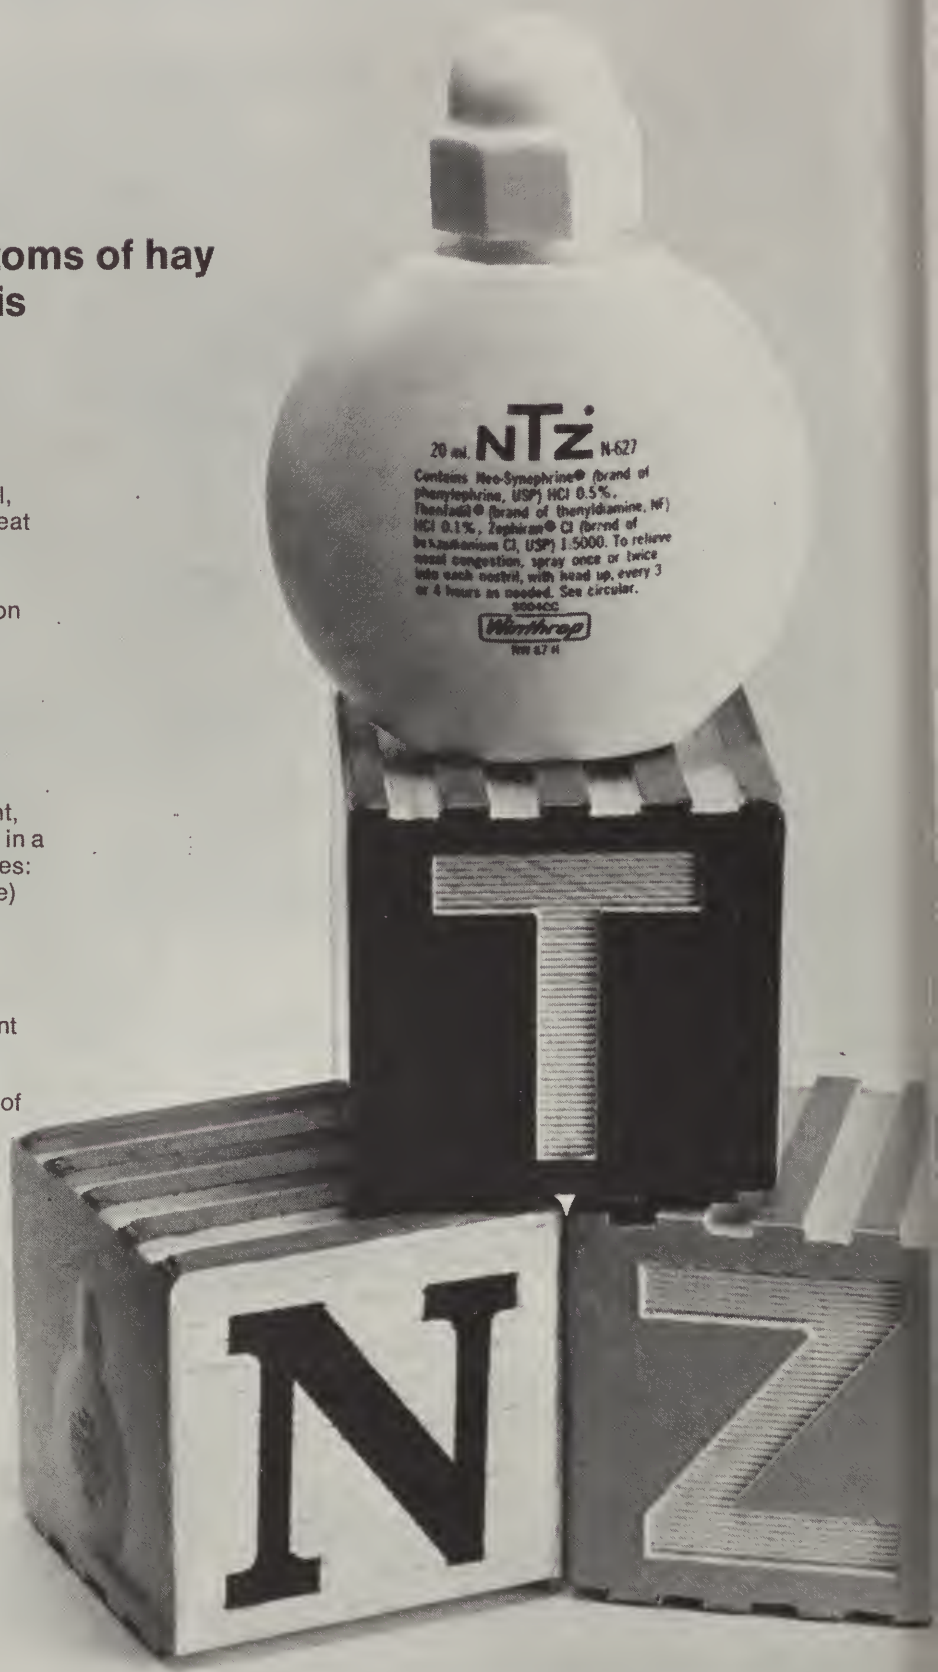
For two years I have been concerned about regulations as published in the "Laws, Rules and Regulations" distributed by the Medical and Chirurgical Faculty of the State of Maryland.

In the December 1966 issue it is stated (regarding laboratory services) that "all billing should be done by the laboratory doing the service. If a clinician and a laboratory share the responsibility of the laboratory procedure, each should send a bill for services rendered." It further states that "it shall be considered unethical for any physician to bill for laboratory services not performed by him or his regularly supervised employed assistants." It is also considered unethical to "collect fees from any insurance company for laboratory services not performed by him or his regularly employed assistants."

Since I consider the word unethical to denote basic dishonesty, I cannot help but resent these regulations. To my knowledge, the medical society has not voiced an active opinion regarding this and I think it is time that they do. Of recent date there has been some question through the insurance carriers regarding this very problem. It would seem that those ethical physicians, who provide the laboratory materials and perform the services required in obtaining specimens and interpreting them, are being unjustly judged. In many instances, laboratory services are done at a much lower cost to a patient than at a hospital laboratory or privately owned local laboratory, and the results have proved consistently accurate. I cannot conceive how it is unethical to pass savings on to patients and provide a greater medical profile and service to them. Also, I have no knowledge of any insurance carrier who is willing to split the cost of laboratory procedures and pay both the laboratory performing the actual determination and the physician who shares the responsibility of obtaining the procedures and associated involved expense. Since the federal government has seen fit to authorize payment to physicians for laboratory services performed in an approved laboratory, it would seem that our local society and the state society should consider discarding what appears to be a bit of "in-fighting" and allow the physician the discretion and respect to which he is entitled. *(From the Montgomery County* Bulletin.)

Respectfully,

MORRILL C. QUINNAM, JR., MD
Silver Spring



as easy as NTZ®

An easy solution to the problem of nasal symptoms of hay fever, colds and sinusitis

- easy to prescribe: just write NTZ Nasal Spray.
- easy to recommend: just say NTZ Nasal Spray.
- easy to use: just one spray in each nostril, quickly followed by a second spray. Repeat q. 3 h. or q. 4 h. for temporary relief.
- easy to dispense: the outer sleeve of the package is removable for easy application of prescription label.
- easy to remember: as easy as NTZ.

But more than a simple vasoconstrictor:
NTZ Nasal Spray affords the well-known benefits of Neo-Synephrine®, 0.5 per cent, the more potent solution (adult strength) in a carefully balanced formula which includes:
Neo-Synephrine (brand of phenylephrine) HCl 0.5 per cent, decongestant
Thenfadil® (brand of thenyldiamine) HCl 0.1 per cent, antihistamine
Zephiran® (brand of benzalkonium, as chloride, refined) Cl 1:5000, wetting agent

Available: NTZ Nasal Spray in squeeze bottles of 20 ml.; NTZ Solution in bottles of 1 oz. with dropper.

prescribe NTZ® Nasal Spray
(contains Neo-Synephrine)

Library and History Committee
ELIZABETH SANFORD
Librarian

library

Hewson on the Blood

The treasures of our library continue to be unearthed, so to speak, at each monthly visit of our Library Consultant. In January we discovered the very rare *Experimental Inquiries* of William Hewson, 1739-74. All three volumes, delineating the author's important researches, fundamental to human physiology, were found in the Library stacks. Hewson, in his first volume of 1772, established the fact that fibrinogen caused blood coagulation; the 1774 (first edition) work "gave the first complete account of the anatomical peculiarities of the lymphatics and described the origin of leucocytes"; the third book (1777) published posthumously, described in its first edition Hewson's additional observations and experiments. Very few medical libraries can boast of complete sets of this very important series of medical classics by one of the Hunters' outstanding students. But in addition, in March, in another part of the Library, Mr. Ash also uncovered (through his book by book inspection of the shelves) the first edition (1771) of the first part of the set, of which the previously found 1772 edition was the first revision. Thus the Med-Chi Library is the proud possessor of a complete set of this outstanding and most important rarity in the fields of blood research and experimental medicine.

Here is another example of the usefulness of our consultant's work. None of these books was entered in the incomplete public catalog of the Library, although we did have a shelf list (inventory) of them, but no record by author or subject. Thus librarians, readers, or reseachers have had absolutely no way of knowing about their existence. Fortunately, the catalog program of the past few years is under efficient professional control and only the older cataloging is in dire need of complete revision in order that we can discover and use the Library's remarkable resources which, Mr. Ash says, make up one of the nation's finest historical and rare medical book collections.

Meetings Here And There

By the time this issue appears the Med-Chi annual meeting will be history and your librarian will have attended the Third International Congress on Medical Librarianship held in Amsterdam May 5-9. The last International Congress was held in Washington in 1963 and convened a colorful collection of librarians from all over the world.

* * *

At the March meeting of the Baltimore Hospital Librarians Association the members voted to plan another meeting of hospital and medical librarians for the annual Tri-State Hospital Association meeting in Washington, December 1-3, 1969.

For such patients, consider **Regroton®**

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

To lower blood pressure and allay anxiety in hypertension.

For brief summary of prescribing information, see next page.

RE-6392

Regroton®

Geigy

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

the once-a-day tablet for anxious hypertensives

Regroton is a combination of two basic antihypertensives designed to lower blood pressure and allay anxiety in hypertension. With Regroton he can keep his shirt on and you can keep his blood pressure down.

Before prescribing, please review carefully the indications, contraindications, warning, precautions, adverse reactions and dosage information below.

Regroton®
Each tablet contains:
chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

Indications: Hypertension.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs.
Use in pregnancy: Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. Increased respiratory secretions, nasal congestion, cyanosis and anorexia may occur in infants born to reserpine-treated mothers.
Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue therapy with this agent two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.
Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Severe salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients.
Adverse Reactions: The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis). drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible.
Average Dosage: One tablet daily with breakfast.
Availability: Pink, single-scored tablets in bottles of 100 and 1000. (B)46-600-C
For details, please see complete prescribing information.

RE-6392

The Serologic Syphilis Test Required for Marriage in Other States

Robert L. Cavenaugh, MD
Director, Bureau of Laboratories
Maryland State Department of Health

Persons in other states who wish to get married in Maryland are indeed fortunate, judging by the amount of trouble and red tape Marylanders must go through if they want to get married in any of the 45 states that require a premarital test for syphilis. Each of these states has its individual, specific regulations and its own forms for certifying to the premarital test. All are different, some calling for a physical examination, some accepting merely the laboratory test, and among them is a wide variety of the types of tests and of laboratories that are acceptable. Moreover, it it obviously impossible for each of these states to provide its certification forms to all the county clerks of every state whose citizens might want to be married within the boundaries of that particular state.

One important uniformity exists: All 45 of these premarital-law states will accept tests performed by the central public health laboratory of any other state. Because of this, furthermore, the Maryland Health Department's Central Laboratory maintains a supply of the proper forms and certificates for all states—and for New York city, District of Columbia, and some provinces of Canada—that require the premarital syphilis test.

The purpose of this article is to inform those concerned, and to ask them to inform their staff representatives, as to the easy and effective method for obtaining the premarital serologic test for syphilis (STS) for marriage in any state (except those listed below which have no such requirements).

States Having No Requirement of Premarital Syphilis Testing

Maryland
Minnesota
Nevada
South Carolina
Washington

The prospective partners in Maryland can go to any health office or to any physician's office, hospital or laboratory. There the blood is drawn into the STS tube, which is a component of the "STS Outfit" available from the Bureau of Laboratories (Central or Branch Laboratories). This "outfit" contains the request form, MB-1-1-Ce, on which the identifying information is to be entered. Essential, of course, is an Additional Entry identifying that it is for a premarital test and naming the state and city in which the marriage is to be performed.

If the physician's office does not have on hand the "STS Outfit" but can provide a clean, stoppered test tube for collecting 5 to 8 milliliters of whole blood, the information that must be submitted with the specimen is as follows:

Physician's name and address, including ZIP code
Patient's full name, address, and county of residence, with the usual data as to age and sex and, if available, the Welfare Number
The date the specimen was taken
The test required
The Additional Entry in large letters at the top of the form:
FOR MARRIAGE IN .....(city),
.....(state).

The specimen is then sent to the Central Laboratory, Bureau of Laboratories, 16 E. 23rd Street, Baltimore, Md., 21218. Specimens received by noon are reported by 4 P.M. the same day. If, as is often convenient, the physician wishes the report delivered to the patient in person, he must unmistakably authorize this. There is no charge for this test, since it is made for the detection of a communicable disease.

Pennsylvania (and a few other states) authorizes the issue of a marriage license upon evidence of a serologic test for syphilis performed in a state-approved laboratory in another state, *provided* such approval is certified on the Pennsylvania form by an authorized official of the approving Department of Health. For this, of course, the form, if not the specimen, must be sent to the Bureau of Laboratories. Further information is under compilation for publication on this subject, which will in all likelihood be covered in Federal regulations effective July 1, 1969 dealing with clinical laboratories operating in interstate commerce.

...you have a lot going for you in the wide range of bacterial infections.

PRESCRIBING INFORMATION. For complete information consult Official Package Circular. **Indications:** Infections due to susceptible strains of Gram-negative bacteria (including Shigellae, *. typhosa* and other Salmonellae, *E. coli, H. influenzae, P. mirabilis, N. gonorrhoeae* and *N. meningitidis*) and Gram-positive bacteria (including streptococci, pneumococci and nonpenicillinase-producing staphylococci).

Contraindications: A history of allergic reactions to penicillins or cephalosporins and infections due to penicillinase-producing organisms.

Precautions. Typical penicillin-allergic reactions may occur, especially in hypersensitive patients. Mycotic or bacterial superinfections may occur. Experience in newborn and premature infants is limited and caution should be used in treatment, with frequent organ function evaluations. Safety for use in pregnancy is not established. In gonorrheal therapy, serologic tests for syphilis should be performed initially and monthly for 4 months. Assess renal, hepatic and hematopoietic function intermittently during long-term therapy.

Adverse Reactions: Skin rash, pruritus, urticaria, nausea, vomiting, diarrhea and anaphylactic reactions. Mild transient elevations of SGOT or SGPT have been noted. Black tongue has been noted in some patients receiving the Chewable Tablets.

Usual Dosage: Adults—250 or 500 mg. q. 6 h. (according to infection site and offending organisms). Children—50-100 mg./Kg./day in 3 to 4 divided doses (depending on infection site and offending organisms). Bacterial meningitis —150-200 mg./Kg./day in 6 to 8 divided doses. Children weighing more than 20 Kg. should be given an adult dose when prescribing orally. In parenteral administration, children weighing more than 40 Kg. should be given an adult dose. Beta-hemolytic streptococcal infections should be treated for at least 10 days.

Supplied: Capsules—250 mg. in bottles of 24 and 100. 500 mg. in bottles of 16 and 100. For Oral Suspension—125 mg./5 ml. in 60, 80 and 150 ml. bottles. 250 mg./5 ml. in 80 and 150 ml. bottles. Chewable Tablets—125 mg. in bottles of 40. Injectable—for I.M./I.V. use—vials of 125 mg., 250 mg., 500 mg., and 1 Gm. Pediatric Drops—100 mg./ml. in 20 ml. bottles.

now she can cope...

thanks to

Butisol SODIUM®
(SODIUM BUTABARBITAL)

the "daytime sedative" for everyday situational stress

When stress is situational—environmental pressure, worry over illness—the treatment often calls for an anxiety-allaying agent which has a prompt and predictable calming action and is remarkably well tolerated. BUTISOL SODIUM (sodium butabarbital) meets this therapeutic need.

After 30 years of clinical use . . . still a first choice among many physicians for dependability, safety and economy in mild to moderate anxiety.

Contraindications: Porphyria or sensitivity to barbiturates.

Precautions: Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression.

Adverse Reactions: Drowsiness at daytime sedative dose levels, skin rashes, "hangover" and systemic disturbances are seldom seen.

Warning: May be habit forming.

Usual Adult Dosage: As a daytime sedative, 15 mg. (¼ gr.) to 30 mg. (½ gr.) t.i.d. or q.i.d.

Available for daytime sedation: Tablets, 15 mg. (¼ gr.), 30 mg. (½ gr.); Elixir, 30 mg. per 5 cc. (alcohol 7%).

BUTICAPS® [Capsules BUTISOL SODIUM (sodium butabarbital)] 15 mg. (¼ gr.), 30 mg. (½ gr.).

this ulcer did not heal...until its surface was cleared of dead tissue and debris

FIRST APPLICATION
ELASE Ointment is applied to a deep ulceration of a finger.

EIGHTEEN DAYS LATER
Healing has progressed rapidly without interruption or interference from any accumulated purulence or necrotic tissue. Greatly reduced size of lesion and minimal scar tissue indicate quality and vigor of healing which is almost complete.

to aid in debridement to facilitate healing in chronic cutaneous ulcers...

Elase® ointment

(fibrinolysin and desoxyribonuclease, combined, [bovine] ointment)

PARKE-DAVIS

By helping to remove dead tissue and debris from the ulcer's surface, ELASE Ointment creates a better environment for the elimination of infection, for healthy granulation...*for healing.* Its lytic enzymes effectively break down DNA in dead leukocytes and other debris...the fibrin in blood clots, serum, and purulent exudates...and the denatured proteins in necrotic tissue. Protein elements of *living* tissue are relatively unaffected. ELASE Ointment is indicated in stasis ulcers and in other infected or inflamed ulcers caused by circulatory disturbances. In cases requiring skin grafting, it is used preoperatively for debridement. For ambulatory patients debridement with ELASE Ointment is a convenient therapy and a regimen likely to be followed. *Precautions:* Observe usual precautions against allergic reactions, particularly in persons with a history of sensitivity to materials of bovine origin or to mercury compounds. *Adverse Reactions:* Side effects attributable to the enzymes have not been a problem at the dose and for the indications recommended. *Discussion:* Successful use of enzymatic debridement depends on several factors: (1) dense, dry eschar, if present, should be removed surgically before enzymatic debridement is attempted; (2) the enzyme must be in constant contact with the substrate; (3) accumulated necrotic debris must be periodically removed; (4) the enzyme must be replenished at least once daily; and (5) secondary closure or skin grafting must be employed as soon as possible after optimal debridement has been attained. It is further essential that wound-dressing techniques be performed carefully under aseptic conditions and that appropriate systemically acting antibiotics be administered concomitantly if, in the opinion of the physician, they are indicated. *Available:* ELASE Ointment is supplied in 30-Gm. tubes containing 30 units (Loomis) of fibrinolysin and 20,000 units of desoxyribonuclease with 0.12 mg. thimerosal (mercury derivative); and in 10-Gm. tubes containing 10 units of fibrinolysin and 6,666 units of desoxyribonuclease with 0.04 mg. thimerosal. ELASE Ointment has a special base of liquid petrolatum and polyethylene; contains sodium chloride and sucrose used during manufacture; is stable at room temperature through the expiration date stated on the package.

"I feel
so light-
headed..."

She's confused...and frightened. Yesterday, her complaint was a brief spell of dizziness. Next week, she may be troubled by prolonged nausea or tinnitus. The symptom of vertigo is a constant problem in geriatrics, and regardless of origin, duration, and frequency, such episodes can result in severe emotional and physical discomfort for the aging patient.

You can help prevent such problems with

BONINE®

(MECLIZINE HCl)

protects most patients against nausea and vertigo up to 24 hours with a single dose.

Whether the symptoms are due to Ménière's syndrome, labyrinthitis, vestibular dysfunction, or cerebral arteriosclerosis, most patients with nausea and vertigo respond remarkably well to Bonine (meclizine HCl). A single dose usually protects up to 24 hours. In difficult cases multiple daily doses may be necessary for maximum response.

One-a-day dosage costs your patients less. And fruit-flavored Bonine chewable tablets are more convenient to take anytime, anywhere—without water. Side effects are infrequent and mild, even with prolonged use.

Precautions: Although the incidence of drowsiness and atropine-like side effects such as dry mouth and blurring of vision is low, the physician should alert the patient to the need for due precautions when engaging in activities where alertness is mandatory. *Use in women of childbearing age:* In weighing potential benefits vs. risk in women of childbearing age, consider the fact that a review of available animal data reveals that meclizine exerts a teratogenic response in the rat. In one study a dose of 50 mg./kg./day (50 times the maximum recommended human dose) produced cleft palate in 2 of 87 fetuses when administered to the rat at critical times during the first 15 days of gestation. At doses of 125 mg./kg./day, meclizine will produce 100% incidence of cleft palate in the rat. At doses of 25 mg./kg./day, decreased calcification of the vertebrae and relative shortening of the limbs were also produced in the rat, but experts disagree as to whether this is a teratogenic response. While available clinical data are inconclusive, scientific experts are of the opinion that this drug may possess a potential for adverse effects on the human fetus. Consequently, consideration should be given to initial use of a nonphenothiazine agent that is not suspected of having a teratogenic potential. In any case, the dosage and duration of treatment should be kept to a minimum.
Supply: 25 mg. scored tablets.

Members of MAMA Attend AAMA Convention

The annual American Association of Medical Assistants' Convention was held during the week of October 7, 1968, in Columbus, Ohio.

Representing the Maryland Association of Medical Assistants were the elected Delegates: Gertrude Gillum, president of MAMA; Dorothy Hartel, president-elect of BAMA, and Nell Chaney. Mabel Young also attended as a representative from Maryland, and she assisted as a page in the House of Delegates.

On Tuesday and Wednesday of the week, the MAMA sponsored a hospitality room. The theme chosen to represent a Maryland tradition was the Baltimore Colts. Dressed as cheerleaders in blue and white outfits, the hostesses served miniature sandwiches and beer.

Dorothy Hartel was nominated for the office of president-elect of AAMA, and although Dorothy did not win the election, she was appointed Vice-Chairman of membership in charge of organization. Mrs. Hartel also served on the reference committee of constitution and bylaws, and represented Puerto Rico in accepting its charter as a new association.

At left:
MAMA representatives at the AAMA convention included Dorothy Hartel, Russell Fisher, MD (former advisor and convention speaker), Gertrude Gillum and Mabel Young.

Baltimore Association of Medical Assistants Adopts Family at Christmas

The Baltimore Association of Medical Assistants successfully completed its annual Christmas project. The funds collected from the membership and friends were more than sufficient to make a poor family happy at Christmas time. Total collections amounted to $138.50.

Delivery to the family was made on Saturday, December 21, 1968. Two cars were completely filled with clothing, toys, gifts, and canned goods. The family was also given a food certificate for $20 plus $25 in cash.

The family was completely stunned by the quantity of the present, and the eyes of the children would have made each member feel very rewarded for having helped.

A jumbo plastic basket was filled with 20 gift-wrapped presents for the family. The committee had purchased pants, shirts, and underwear, and had filled stockings with candy and various items.

In addition, the committee brought joy to an elderly lady who is bedridden, by purchasing a new robe and slippers for her. She was overwhelmed when presented with the lovely gift-wrapped presents.

Wicomico County Association of Medical Assistants Installs New Officers

At the annual Christmas party of the Wicomico County Medical Assistants the new officers for the year were installed. The officers are as follows:

Doris Ward—President
Judy Terlson—President-Elect
Barbara Hopkins—Secretary
Pat Kelly—Treasurer

BAMA Installs New Officers at the Annual Christmas Party

On December 10, 1968, Eleanor Mainhardt, CMA, installed the newly elected officers of the Baltimore Association of Medical Assistants. The new officers are:

Dorothy Hartel—President
Peggy Bury—President-Elect
Rita Cobry—Vice-President
May Thompson—Recording Secretary
Valerie Hachtel—Corresponding Secretary
Dorothy Walker—Treasurer

During the months of December and January the new committee chairmen were appointed and are as follows:

Rita Cobry—Membership
Eleanor Mainhardt—Nominating
Dorothy Walker—Budget and Finance
Eileen Adams—Registration
Ann Shultz—Public Relations
Thelma Dorsett—Education
Eleanor Mainhardt—Judicial
Peggy Bury—Constitution and Bylaws
Valerie Hachtel—Program
Eleanor Stuck—Arrangements
Margaret Stump—Fund Raising
Lillian Burford—Telephone Contact

(Continued next page)

Newly elected officers of BAMA are *(from left)* Peggy Bury, president-elect; Dorothy Walker, treasurer; May Thompson, recording secretary; Rita Cobry, vice-president, and Dorothy Hartel, president.

Montgomery County Chapter Installs New Officers

On February 12, 1969, the Montgomery County medical assistants held their annual Bosses' Night and installed the new officers. The newly elected officers for the year are:

Frances Whittaker—President
Jean Klopfer—President-Elect
Hazel Wright—Vice-President
Nancy Phelps—Secretary
Margaret Eid—Treasurer

John T. Miller, PhD, Speaks to BAMA

The monthly meeting of the Baltimore Association of Medical Assistants was held on February 11, 1969, at the Medical and Chirurgical Faculty of Maryland. The guest speaker for the evening was John T. Miller, PhD.

Dr. Miller spoke on the "Art of Immunology" and his presentation proved to be interesting and informative to the audience.

Dr. Miller

José Martinez, MD, Speaks to Medical Assistants

At the monthly meeting of the Baltimore Association of Medical Assistants held at the Penn Hotel on March 11, 1969, José Martinez, MD was the guest speaker and presented a very interesting talk on "Radioisotopes."

Dr. Martinez briefly explained the origin of nuclear medicine and the growing importance of this field of medicine. Generally speaking, by the use of radioisotopes in diagnostic purposes the doctor is assisted in his final diagnosis of illness by being told what the patient does not have, rather than what the patient does have. Consequently, radioisotopes become a useful tool by which the doctor can save the patient much expense and many times much discomfort.

During his talk, Dr. Martinez showed slides which illustrated the manner in which radioisotopes are used diagnostically. He also explained the various chemical elements involved in proper scanning and the types of tests now available to the patient.

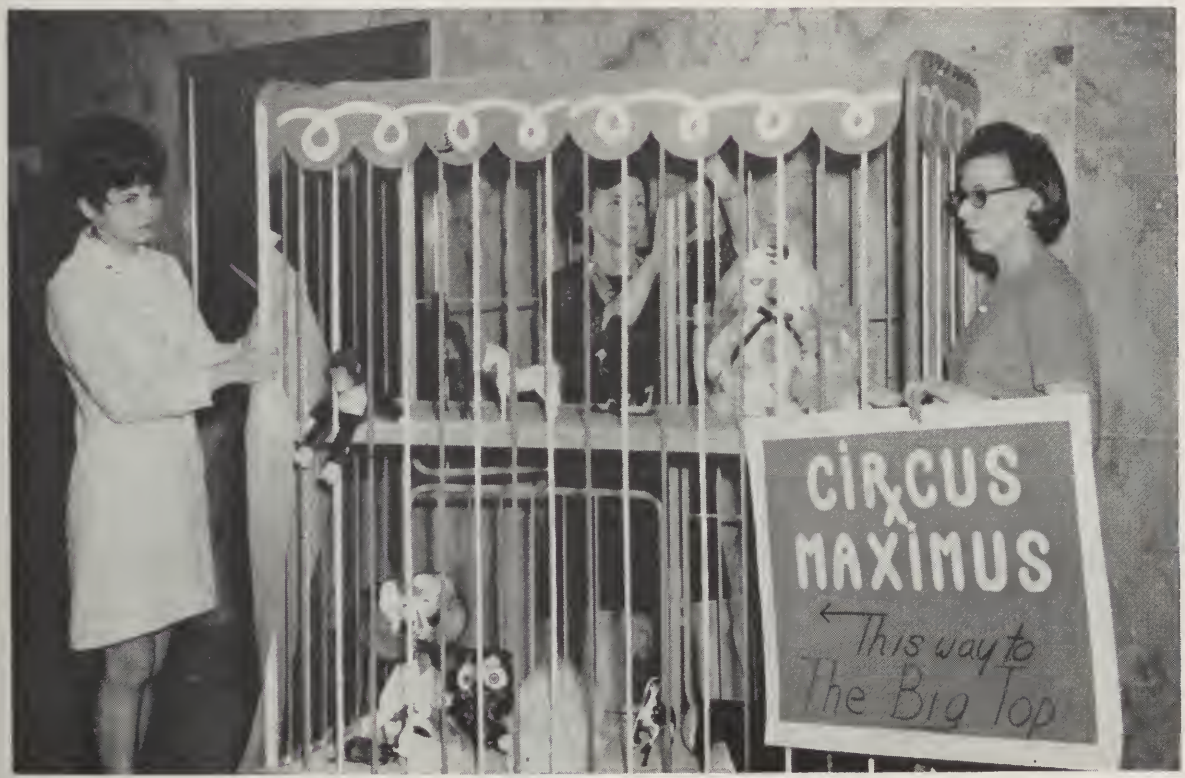
José Martinez, MD, was born in Alexandria, Egypt, which is now the United Arab Republic. He was graduated from Alexandria University School of Medicine in 1957, and came to Baltimore in 1958. He trained in internal medicine at Church Home and Hospital. He then received his training in nuclear medicine at The Johns Hopkins University School of Medicine and the Oak Ridge Institute of Nuclear Studies. Presently, he is in private practice of internal medicine, as well as associate medical director of The Baltimore Regional Joint Board of Amalgamated Clothing Workers of America Health and Welfare Fund. Dr. Martinez is also director of the Division of Nuclear Medicine at Lutheran Hospital.

Medical Assistants' Week

Each year, for the past three years, the week preceding the annual meeting of the Maryland Association of Medical Assistants has been proclaimed MEDICAL ASSISTANTS' WEEK by the Governor, in order to call attention to the dedicated approach to duty which characterizes the physician's assistant. The desire to help those in distress to the best of their ability, and the increasingly important contributions in the field of education for paramedical workers by this group has earned it the attention and respect of the nation, since it is a national organization.

During this week, members of the Baltimore Association of Medical Assistants donated and operated a coffee and doughnuts bar for the aid and comfort of their physician employers who attended the annual meeting of the Medical and Chirurgical Faculty of Maryland at the Alcazar from April 9-11, 1969. This association of workers in the health field is the only such group approved and endorsed by the American Medical Association.

The week's activities ended with the 9th Annual Meeting of the MAMA which was held at the Holiday Inn on Saturday, April 12, 1969. The business meeting and election of officers were conducted as usual, interspersed with lectures by two prominent physicians. William Kirby, MD, director of Administrator Research, Department of Medicine and Surgery, Veterans Administra-



tion, spoke on "Some Approaches to the Medical Care Problem." Otto C. Brantigan, MD, professor of clinical anatomy and professor of surgery at the University of Maryland, lectured on "Help Needed in Surgery."

Mrs. Richard Daniel, Physical Therapy technician at Church Home and Hospital, was installed as President of the association at the banquet which was held following cocktails in the evening. Mr. T. G. Whedbee, Jr., Director of Church Home and Hospital, was Master of Ceremonies at the banquet and Rev. Thomas Subock, of the Baltimore Council of Churches, whose residence is in Annapolis, was Chaplain for the evening.

Barbara Daniel
New President of MAMA

Below:
Barbara Daniel, Ann Shultz and Nell Chaney are pictured busily preparing for MAMA's Annual Meeting, and the Paint and Powder Show, which was held earlier this month for the benefit of Church Home and Hospital.

The State of Maryland

Executive Department

GOVERNOR'S PROCLAMATION

Doctor's Day
March 30, 1969

WHEREAS, Medical men and women labor long hours caring for the sick and preventing human misery and suffering; and

WHEREAS, The horizon is bright with new hopes in the skills and knowledge of those devoted to the area of healing; and

WHEREAS, The world has one of its greatest centers in Maryland for developing and disseminating advanced knowledge in medicine and surgery; and

WHEREAS, With the help of our fine surgeons and physicians, our State has a pioneer plan of giving medical aid to those unable to support their needs; and

WHEREAS, The people of Maryland are grateful to the medical profession for its vital contributions to the health of our population;

NOW, THEREFORE, I, MARVIN MANDEL, Governor of the State of Maryland, do hereby proclaim the 30th Day of March, 1969, as

DOCTOR'S DAY

in Maryland, and I urge my fellow citizens to give special thanks to the many unselfish men and women who practice medicine among us.

GIVEN Under My Hand and the Great Seal of the State of Maryland, at the City of Annapolis, this 11th Day of February, in the Year of Our Lord, One Thousand Nine Hundred Sixty-Nine.

By the Governor:

Marvin Mandel

Blair Lee III
Secretary of State

MRS. HARRY L. BERMAN, EDITOR

Doctors' Day Observances Around the State

Sunday, March 30 was Doctors' Day throughout the State. Each year, one day is set aside to express our appreciation to the physicians of Maryland for their unselfish services.

Carnations and conviviality . . . Bouquets of red carnations were placed in Carroll County General, Harford Memorial, Sacred Heart and Memorial (Cumberland) and the four Montgomery County hospitals by local medical society auxilians. Patients were remembered with tray favors. Luncheons, dinners and dances prevailed over Maryland's countryside.

Prince Georges General Hospital was the setting for a Doctors' Day luncheon, planned by the hospital administrators. Auxilian hostesses presented a red carnation to each physician, while posters in the hospital and local libraries complemented the theme.

On the Eastern Shore Four Counties physicians enjoyed a dinner in their honor; and wives of Harford physicians pooled their talents for a delightful covered-dish dinner.

At St. Joseph's Hospital, Baltimore County auxilians presented a medical book to commemorate the day; while Washington County auxilians presented books to the Wroth Memorial Library.

The Enoch Pratt Library devoted one of its Cathedral Street windows to the medical professional with an impressive display arranged by the Baltimore City auxilians. The metropolitans also contributed their annual check to AMAERF to be divided between the two medical schools.

One of the loveliest tributes on this special day was a remembrance by the Harford County auxiliary. AMAERF memoriam cards were sent to widows of medical society members.

The Woman's Auxiliary to the Montgomery County Medical Society presented a bouquet of red carnations to the four hospitals in Montgomery County; and People's Drug Stores sponsored a cocktail reception at the Indian Springs Country Club in honor of the devoted physicians of the community.

The receiving line at the cocktail reception in honor of the doctors of Montgomery County included (*from left to right*): Mrs. John McHugh, Mr. John McHugh, director of Professional Services of the Peoples Drug Stores; Mrs. Mertin White, wife of the president of the Montgomery County Medical Society; Mr. George P. Burrus, president of Peoples Drug Stores; and Mrs. Burrus; Dr. Gordon Smith and Mrs. Smith, president of the Woman's Auxiliary to the Montgomery County Medical Society.

MEDICAL NEWS

The American College of Gastroenterology, in cooperation with William H. Rorer, Inc., of Fort Washington, Pa., announces the **1969 Rorer Awards Contest for the best papers in Gastroenterology.**

All papers submitted must not have been published previously. They must represent original work in gastroenterology, or an allied subject, and must not have been presented at meetings of any national society.

The First Prize is $500 and a three-year subscription to *The American Journal of Gastroenterology.* The Second Prize is $300 and a two-year subscription, and the Third Prize is $200 and a one-year subscription. The awards will be made at the Annual Convention Banquet of the College in Houston, Texas in October 1969.

All entries must be received no later than June 15, 1969, and should be addressed to the Research and Education Committee, American College of Gastroenterology, 299 Broadway, New York, N. Y. 10007.

* * *

James E. Carson, MD, Commissioner of the Department of Mental Hygiene, has been elected President of the Maryland Psychiatric Society for the 1969-1970 year.

Russell R. Monroe, MD, Professor of Psychiatry of the University of Maryland School of Medicine, has been named President-Elect. Named Secretary-Treasurer is **Gertrude M. Gross, MD,** Director of the Baltimore City Psychiatric Day Center, and newly elected Councilor is **Courtney Clower, MD,** Director of Psychiatric Education and Training of the Spring Grove State Hospital.

* * *

The American Academy of General Practice in Kansas City, Missouri will pay a consulting fee and expenses of qualified consultants to help hospitals and medical schools plan and set up graduate and undergraduate training programs in family practice, according to **R. Neil Chisholm, MD,** Chairman of the Academy's Commission on Education.

Dr. Chisholm said that the consultants will be reimbursed for actual expenses and paid an honorarium of $100 for each day of consultation, with a limit of two days for each visit. He added that educators and practicing physicians who feel they would qualify, and would like to do this kind of work, should contact him through Academy Headquarters, Volker Boulevard at Brookside, Kansas City, Mo. 64112.

* * *

Manuel J. Balseiro, MD, has been certified as a Fellow of the American College of Anesthesiologists.

* * *

Gilbert D. Barkin, MD, was named to the Board of Directors of the International Society of Certified Allergists at a meeting in Mexico City, December 1, 1968.

* * *

Herbert Gross, MD, of Silver Spring and the University of Maryland Psychiatric Institute, was certified by the American Board of Psychiatry and Neurology at its meeting in Chicago, October 7-8, 1968.

* * *

Gerald Gelford, MD, and **David Cromwell, MD,** published an article entitled, "Methysergide, Retroperitoneal Fibrosis and Rectosigmoid Stricture" in the November 1968 issue of *Am J of Roentgenol, Radium Therapy and Nuclear Medicine.*

* * *

Lewis H. Dennis, MD, published a paper entitled, "Alteration of Fibrinolysis and Blood Coagulation Induced by Exercise and the Effect of Beta Adrenergic Receptor Stimulation" in *The Lancet,* December 1968.

* * *

Evan Ragland Farmer, a medical student at The Johns Hopkins University, has been awarded a foreign fellowship

to Friends Hospital in Kisumu, Kenya. Accompanied by his wife, he will have an opportunity to obtain supervised medical experience in developing areas of the world.

His foreign fellowship, and 30 others, were made possible by a grant from Smith Kline & French Laboratories. With the current selection, the Association of American Medical Colleges has awarded a total of 308 fellowships in the last ten years for work and study in more than 50 countries of Africa, Asia, Latin America, and Oceania.

* * *

The Poison Control Center at The Johns Hopkins Hospital has a member of the house staff available 24 hours a day for over-the-phone advice, and for medical treatment.

The Baltimore City Poison Control Centers are: University Hospital, Redwood and Greene, 955-2121 (ask for poison control); Baltimore City Hospitals, 4940 Eastern Ave., 342-0800; The Johns Hopkins Hospital, 601 N. Broadway, 955-5000 (ask for poison control); Sinai Hospital, Greenspring at Belvedere, 367-7800 (ask for poison control).

* * *

Robert H. Kennedy, MD, Former Director of Field Program Committee on Trauma, American College of Surgeons, has received a special Certificate of Commendation from the Division of Emergency Health Services of the U. S. Public Health Service. This special award was presented to Dr. Kennedy at the Annual Meeting of the Committee on Trauma in Baltimore, Maryland on January 24, 1969.

The award was given to Dr. Kennedy "for his sincere interest, professional guidance, contribution in time and skills, dedication and distinguished service in advancing the cause of improved care and treatment of trauma victims." The Certificate of Commendation was signed by William H. Stewart, MD, Surgeon General; Henry C. Huntley, MD, Director of Emergency Health Services; and Joseph K. Owen, MD, Chief of the Hospital and Ambulance Services Branch.

* * *

The New York University Medical Center announced the appointment of **Mathew H. M. Lee, MD,** as Director of the Rehabilitation Medicine Service at Goldwater Memorial Hospital. Dr. Lee replaces Michael Dasco, MD, who resigned after more than 25 years of service.

Born in Hawaii, Dr. Lee received his undergraduate degree from The Johns Hopkins University in 1953, and was graduated from the University of Maryland School of Medicine in 1956 with honors.

* * *

Rex Boland Conn, Jr., MD, has become Director of a reorganized Department of Laboratory Medicine at The Johns Hopkins Hospital. In his new position, Dr. Conn will head the hospital's clinical laboratories, staffed by more than 200 people.

He also accepted an appointment at The Johns Hopkins University School of Medicine as Professor of Laboratory Medicine in a newly created division of the Department of Pathology. Dr. Conn plans to begin work to form a School of Medical Technology, and a residency training program in clinical pathology.

* * *

Walter Modell, MD, chairman of The Merck Company Foundation's six-member selection committee of distinguished scientists, announced the **winners of the 1969 Merck Sharp & Dohme International Fellowships in Clinical Pharmacology.** They are: Jose Luis Diaz, MD, Mexico; Takashi Ishizaki, MD, PhD, Japan; Cesare Sirtori, MD, Italy; and Milan Slavik, MD, Czechoslovakia.

The Fellowship Program, begun in 1964, is designed to help relieve the world-wide shortage of clinical pharmacologists, physicians who have attained expert knowledge through specialized study and who devote themselves to the evaluation of the usefulness and safety of new drugs before they are made generally available to physicians. The program finances up to two years of study in the United States for each appointee. Full tuition, fees, and basic travel expenses are paid. The grants also provide a basic stipend of $500 monthly, plus a family allowance of $100 monthly for a wife, and $50 for one child or $100 for two or more children.

Dr. Slivak, 38, is engaged in research on immunosuppressive drugs at the Institute of Phramacology of the Czechoslovak Academy of Science in Prague. He received the MD degree from Charles University in Prague in 1960 and is working for the PhD degree in Clinical Pharmacology. He will undertake his training in the United States with Dr.

Albert Sjoerdsma, Chief, Experimental Therapeutics Branch of the National Heart Institute in Bethesda.

The purpose of the grants is to spread knowledge of the science of clinical pharmacology around the world. Therefore, the applicants had to promise to return to their own countries upon completion of their training in the United States.

* * *

Lester M. Dyke, MD, who retired last January as director of the University of Maryland Health Service, will go into private practice in Tilghman, Maryland, a small town of 1400 residents, mostly watermen. "I don't think," he says, "those people should have to drive a 25-mile round trip to see a doctor."

There is other evidence that Dr. Dyke—a retired Army Colonel—isn't going in for full retirement. He will remain until June with the Health Service as a part-time staff physician working with his successor and former assistant director, **U. R. Merikangas,** who is now director.

* * *

A new specialty of Family Medicine was officially recognized by organized medicine in Chicago when the Advisory Board for Medical Specialties and the Council on Medical Education of the American Medical Association approved a specialty board in family practice. The medical regulatory bodies met at the Palmer House.

The new specialty, 20th of the profession's primary specialty groups, brings medicine full-circle since the trend toward specialization began after World War II. With the creation of the specialty of Family Medicine, the family doctor himself now can become a specialist in his own right.

* * *

Proposals for revamping the American health care system to improve its accessibility and productivity were made by the national head of Blue Cross.

Speaking at the Detroit Economic Club, **Walter J. McNerney, president of the Blue Cross Association,** proposed the creation at the national level of a "Council of Health Advisors—advisory to the President in matters pertinent to the health and welfare problems of our society. . . ."

* * *

Theodore Cooper, MD, director of the National Heart Institute, has announced the appointment of **Donald S. Fredrickson, MD,** to the post of Director of Intramural Research. In this position, Dr. Fredrickson will be charged with over-all planning, direction, and coordination of the Heart Institute's intramural cardiovascular research programs.

Dr. Fredrickson's research at NHI has earned him international recognition as an authority on fat transport in the circulation, and on diseases of lipid metabolism. Recently, he and his colleagues introduced a new system for using plasma lipoprotein patterns to identify and classify excesses of blood cholesterol and other fats. With it they have demonstrated several new syndromes not previously recognized as separate diseases.

* * *

The American Council of Otolaryngology, a new medical organization, has been incorporated in the District of Columbia to represent the patient care interests of the nation's estimated 6,000 otorhinolaryngologists.

The new Council, which will establish a national office here this year, plans to provide leadership for national, regional, state, and local groups in otolaryngology in order to provide better patient care in this specialty field.

The Chairman of the Board, elected by the organizing committee, is **Jerome A. Hilger, MD,** of St. Paul, Minn. The other officers elected to the Council are: **John E. Bordley, MD,** Baltimore, vice-chairman; **Paul Holinger, MD,** Chicago, president; **Walter P. Work, MD,** Ann Arbor, Mich., vice-president; and **Jack R. Anderson, MD,** New Orleans, secretary-treasurer.

Dr. Bordley

* * *

Harvey L. P. Resnik, MD, has been named Chief of the National Institute of Mental Health's Suicide Prevention Program.

Dr. Resnik, 39, is an internationally known suicidologist and comes to the Institute from Buffalo, New York, where he was director of psychiatry at E. J. Meyer Memorial Hospital. He is on leave of absence as Professor and Deputy Chairman of the Department of Psychiatry at the State University of New York in Buffalo.

* * *

Daniel R. Robinson, MD, medical director for the 11-state southeast region of the Veterans Administration, has been named Director of the San Francisco VA Hospital.

Dr. Robinson came to the Veterans Administration in April 1953, almost 20 years after he received his MD from the University of Maryland School of Medicine. For more than ten years, he has been responsible for VA medical care extended to the 4.5 million veterans in the southeastern states.

Before assuming his present position in July 1969, he was chief of staff of the Indianapolis VA Hospital and director of the Dwight, Ill., and Ft. Howard, Md., hospitals.

* * *

The Montgomery County Board of Education has established a **Community Drug Alert Program.** Several physicians have been scheduled to speak on the panels, the first of which was held on January 13, 1969, at Bethesda-Chevy Chase High School. The success of this first program was reported upon in the **Montgomery County Sentinel.**

* * *

The Board of the Maryland Medical Service, Inc. has re-elected **J. Sheldon Eastland, MD,** to its chairmanship. **Charles F. O'Donnell, MD,** is the new Board vice president. F. Edward Rugemer, secretary; Denwood N. Kelly, president; Edward F. Hassen, vice president, and William C. Flook, treasurer, are the other officers elected.

* * *

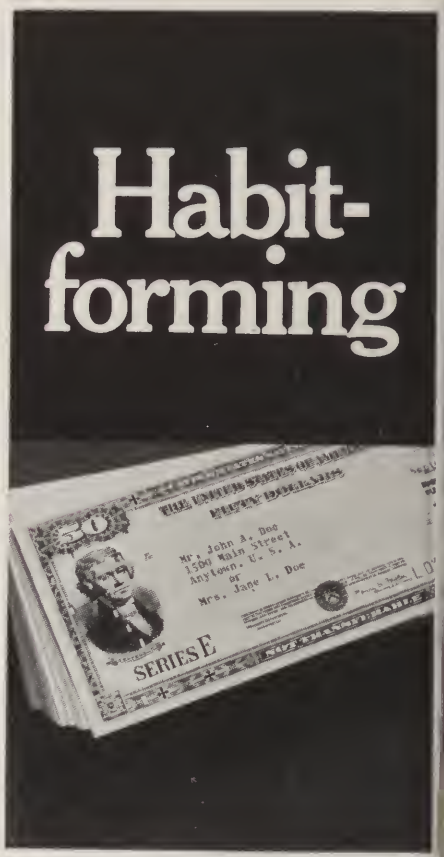
Frank T. Barranco, MD, has completed requirements for the American Board of Orthopedic Surgery and has been named a Diplomate of the Board.

* * *

The newly elected President of the Eastern Section of the American Congress of Rehabilitation Medicine is **B. Stanley Cohen, MD.**

* * *

Julius S. Piver, MD, and **John R. Marchese, MD** were recently certified as Diplomats of the American Board of Obstetrics and Gynecology.



* * *

Doctors John C. Devers, J. Peter Murphy and **Robert W. Zimmerman** participated as speakers on the program of the Southern Maryland Dental Society Postgraduate Clinic, Feb. 21-28, at the Macuto-Sheraton Hotel, Caracas, Venezuela.

et's be specific about Campbell's Soups...
and *reducing diets*

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,400 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

No two women are quite alike...

and no other oral contraceptive is quite like Ovulen-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

The progestin is distinctive, and for some women this may mean a different clinical response. The Compack® tablet dispenser is distinctive; its functional simplicity makes it virtually patient-proof. The acceptance of Ovulen-21 is distinctive... together with Ovulen®, it is more often prescribed than any other individual contraceptive product currently available.

Indication—Oral contraception.

Contraindications—Thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia, undiagnosed abnormal genital bleeding.

Warnings—Watch for the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism, retinal thrombosis); if present or suspected discontinue the drug immediately.

British studies reported in April 1968[1,2] estimate there is a seven- to tenfold increase in mortality and morbidity due to thromboembolic diseases in women taking oral contraceptives. In these controlled retrospective studies, involving 36 reported deaths and 58 hospitalizations due to "idiopathic" thromboembolism, statistical evaluation indicated that the differences observed between users and non-users were highly significant. The conclusions reached in the studies are summarized in the table below:

Comparison of Mortality and Hospitalization Rates Due to Thromboembolic Disease in Users and Non-Users of Oral Contraceptives in Britain.

Category	Mortality Rates		Hospitalization Rates (Morbidity)
	Age 20-34	Age 35-44	Age 20-44
Users of Oral Contraceptives	1.5/100,000	3.9/100,000	47/100,000
Non-Users	0.2/100,000	0.5/100,000	5/100,000

No comparable studies are yet available in the United States. The British data, especially as they indicate the magnitude of the increased risk to the individual patient, cannot be applied directly to women in other countries in which the incidences of spontaneously occurring thromboembolic disease may differ.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or sudden onset of proptosis, diplopia or migraine. Withdraw medication if papilledema or retinal vascular lesions are found.

Since the safety of Ovulen in pregnancy has not been demonstrated, it is recommended that pregnancy be ruled out for any patient who has missed two consecutive periods before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the first missed period.

A small fraction of the hormone agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—Pretreatment physical examination should include special reference to the breasts and pelvic organs, and a Papanicolaou smear.

Endocrine and possibly liver function tests may be affected by Ovulen. Therefore, it is recommended that such tests if abnormal be repeated after the drug has been withdrawn for two months.

Pre-existing uterine fibromyomas may increase in size under the influence of progestogen-estrogen preparations.

Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation.

In breakthrough bleeding, and all irregular vaginal bleeding, consider nonfunctional causes. Adequate diagnostic measures are indicated in undiagnosed vaginal bleeding.

Carefully observe patients with a history of psychic depression and discontinue the drug if severe depression recurs.

Any possible influence of prolonged Ovulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study.

A decrease in glucose tolerance has occurred in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be observed carefully while receiving Ovulen.

Because of the effects of estrogens on epiphyseal closure Ovulen should be used judiciously in young patients in whom bone growth is not complete.

The age of the patient constitutes no absolute limiting factor, although Ovulen therapy may mask the onset of the climacteric.

The pathologist should be informed of Ovulen therapy when relevant specimens are submitted.

Adverse Reactions—A statistically significant association has been shown between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: cerebrovascular accidents, neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement, secretion), change in weight, changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, allergic rash, rise in blood pressure in susceptible individuals, mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme and nodosum, hemorrhagic eruption, itching.

The following laboratory results may be altered by oral contraceptives: hepatic function: increased sulfobromophthalein and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T^3 uptake values; metyrapone test; pregnanediol determination.

In the complex picture of moderate to severe anxiety...

there is a new reason for prescribing Mellaril (Thioridazine HCl)

effectiveness in mixed anxiety-depression

Long recognized for its usefulness in the treatment of moderate to severe anxiety, Mellaril is now also known to be effective against mixed anxiety-depression.

Often the symptoms of anxiety states are difficult to sort out—even with the most careful probing. The patient may manifest symptoms of agitation, restlessness, insomnia, somatic complaints. But what of the depression that may be mixed in the total picture? It is reassuring to know that Mellaril may be prescribed—with strong possibilities of success—when there is anxiety alone or a mixture of anxiety and depression.

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.

Contraindications: Severe central nervous syste depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients wh have previously exhibited a hypersensitivity reac (e.g., blood dyscrasias, jaundice) to phenothiazin Phenothiazines are capable of potentiating centr nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.

Precautions: There have been infrequent reports leukopenia and/or agranulocytosis and convulsi seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmenta retinopathy may be avoided by remaining within recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., drivin Orthostatic hypotension is more common in fem than in males. Do not use epinephrine in treatin drug-induced hypotension. Daily doses in excess 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*— Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism an other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomi Nervous System*—Dryness of mouth, blurred vis constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*— Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urtic type, photosensitivity. *Cardiovascular System*— Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilize including Mellaril (thioridazine hydrochloride). While there is no evidence at present that these changes are in any way precursors of any signifi disturbance of cardiac rhythm, several sudden a unexpected deaths apparently due to cardiac arre have occurred in patients previously showing electrocardiographic changes. The use of periodi electrocardiograms has been proposed but woul appear to be of questionable value as a predictiv device. *Other*—A single case described as parotid swelling.

Mellaril®
(Thioridazine HCl)
25 mg. t.i.d.

for moderate to severe anxie and mixed anxiety-depressi

SANDOZ SANDOZ PHARMACEUTICALS, HANOVER, N. J.

What's in a Name?

"What's in a name? That which we call a rose,
by any other name would smell as sweet."

That may have been Romeo's opinion, but so far as the Medical and Chirurgical Faculty's members are concerned no other nomenclature gives off the same aroma of tradition and heritage. In fact, an attempt in 1962 to effect a simplification and modernization of the Faculty name was confounded by tradition lovers who rejected, out of hand, any such effort. Not so, they said, when the Faculty's title was called antiquated and cumbersome and not indicative of dynamic leadership.

The words "chirurgical" and "faculty" in the name may be difficult to spell, and perhaps even harder to define, but in the words of objectors to the resolution before the society's 1962 House of Delegates, it was ". . . presumptuous to tamper with the name of a society which . . . served the State of Maryland with diligence and honor (so) many years."

The Medical and Chirurgical Faculty of the State of Maryland may indeed bear archaic words (the term "chirurgeon" stems from French and Greek and is defined as someone who does something with the hands), but they have been the medical society's sole possession since a special act of the Maryland Legislature in January 20, 1799, created the body.

Actually, Maryland physicians may feel heartened that the original term used to refer to physicians of Baltimore, was not adopted since they were then referred to as The Practitioners of Physic. In comparison, even the word "Faculty", used to connote a person's calling or profession is less redolent of archaic medical practice.

Maryland was the seventh of the original states to establish a state medical society through legislative act and, in fact, the charter met with opposition in its passage through the Legislature and for some years members were in a state of constant apprehension that the legislators would seize upon some pretext to annul it.

It would be interesting to know how the 101 doctors of Maryland in the original corporation came up with the French-Greek title accorded the medical society in 1799, but even that tireless annotator of the medical annals of Maryland from 1799-1899, Dr. Eugene Fauntleroy Cordell, was unable to shed any light on the authorship of the act creating the body. Dr. Cordell notes specifically: ". . . It is a singular fact that in all the researches of the writer, he has never seen or heard of any manuscript relating to the first meeting . . . not a single letter or document was offered making any allusion whatsoever to it." In addition, Dr. Cordell states that the last survivor, Dr. Ashton Alexander, who died in 1855 and who had been the first secretary, never once made allusion to the creation of the charter or the naming of the medical society.

It is noteworthy, however, that at one point in the preamble to the act to establish and incorporate the organized physicians, it is referred to as "a Medical and Chirurgical Faculty or Society of Physicians and Surgeons in the said State . . ."; so it would appear that even then there was a need to define chirurgeons and faculty as surgeons and society, respectively.

If Maryland's medical society bears a more sophisticated cognomen than any other in the union, this is not really unusual for Maryland where things are just a little different than elsewhere. Only in Baltimore, for instance, is the Bachelors' Cotillon spelled without the "i" making it, by definition in the French dictionary, a petticoat rather than a dance figure. But perhaps it is fitting that Maryland's medical society should have a name derived from the Greek like that of the Vice President of the United States whose name became a household word even, if not too many people can pronounce it: Spiro T. Agnew, that is.

Human Kidney Transplantation:

Renal homotransplantation, although still developmental, has already proven to be an effective treatment for many patients dying of renal terminal failure. During the five years from January 1963 through January 1968, 170 transplants have been performed in 145 patients at the Cleveland Clinic Hospital. Patients receiving kidneys from living related donors can expect at least a 75% one-year survival rate; those receiving kidneys from non-living donors average about a 50% one-year survival. The majority of patients surviving the first critical year live in reasonably good health for at least several years thereafter.

Improvements in immunosuppressive drug therapy, methods for matching donor and recipient, and logistics of organ procurement and preservation are badly needed. If efforts in these areas are expanded on a national scale, renal homotransplantation should become standard treatment for many forms of advanced kidney disease in the very near future.

Present Status

BRUCE H. STEWART, MD
RALPH A. STRAFFON, MD
Dept. of Urology
Cleveland Clinic Foundation
Cleveland, Ohio

and Projected Future

During the past decade the type of treatment available for terminal renal failure has dramatically changed. The use of intermittent hemodialysis and renal homotransplantation has kept many patients alive who were otherwise doomed to an early demise.

In 1954 the first successful human kidney transplant was performed between identical twins at the Peter Bent Brigham Hospital.[1] By 1960, an effective form of immunosuppressive drug therapy had evolved,[2-3] and it became possible to transplant kidneys between related, but non-identical persons.[4-6] As better logistics were developed, it soon became possible to utilize non-living donors on a relatively wide scale,[7] thus eliminating the moral and ethical problems faced in operating upon live, healthy donors.

The latest report of the Human Kidney Transplant Registry lists 1187 primary and secondary renal transplants performed throughout the world.[8] As of February 1968, 170 transplants have been performed on 145 patients at the Cleveland Clinic Hospital; 123 transplants involved non-related, non-living donors, and 47 involved living donors. As a result of this experience it is felt that renal transplantation, although still in the developmental stage, can keep a significant percentage of properly selected patients in good health for long periods of time. Details of currently employed techniques will be discussed, as well as several areas where improvement can and must be made in the near future.

Recipients

Selection—All patients must be in terminal renal failure and require dialysis to maintain life. It is preferable to have a patient under the age of 50, free of other systemic disease, and in whom a reasonable outlook for productive life exists if renal failure can be corrected. Uncooperative or emotionally disturbed patients must, of necessity, be excluded, as careful follow-up studies and treatment are essential for success.

Preparation

(a) *Hemodialysis:* Homeostasis is maintained in all patients by repeated hemodialysis, utilizing either an indwelling Silastic-Teflon arteriovenous shunt,[9] or a surgically created arteriovenous fistula.[10]

(b) *Nephrectomy:* Bilateral nephrectomy, utilizing a midline upper abdominal incision, is done before transplantation whenever possible, for the following reasons: (1) to aid in the control of severe hypertension which is often ameliorated by a renoprival state; (2) to remove a potential source of infection in patients with chronic pyelonephritis; (3) to allow space to insert the transplant in patients with large polycystic kidneys; (4) to provide the patient's own ureter for anastomosis in selected patients; and (5) to provide a recipient in whom subsequent operations with possible complications will not be necessary once transplantation has been done.

(c) *Thymectomy and Splenectomy:* Transcervical *thymectomy* has been carried out by Dr. George S. Crile, Jr., in randomized patients at the time of bilateral nephrectomy. The advantage of thymectomy will not become apparent until immunosuppressive drug therapy is stopped, and the individual's capacity to reestablish an effective system of immunity is thus tested. It is still too early to assess the long-term value of thymectomy in this regard, although to date it, at least, has not caused any increased morbidity.

Splenectomy has been done in many patients in an effort to stimulate the production of leukocytes so larger doses of immunosuppressive drugs can be safely used. However, to date, our results have not yet shown that splenectomy is clearly effective in this regard. The spleens that are removed are now being used for the production of antilymphocytic globulin, which is currently employed in the immunosuppression regimen, as will be discussed later.

(d) *The Waiting Period:* If the patient has a suitable live donor, both donor and recipient can be admitted to the hospital for elective transplantation some two to three weeks after bilateral nephrectomy. If the patient is to receive his kidney from a non-living donor, however, the waiting period may be considerably longer. After recovery from nephrectomy, the recipient is maintained on intermittent hemodialysis and lives outside the hospital, coming in twice weekly for dialysis. These patients live near the hospital so that they can be contacted easily when death of a potential donor seems imminent. This waiting period may last several months, depending upon the availability of a suitable donor. **An increase in awareness of this problem by both the medical profession and the lay public is vital if the short supply of donor organs is ever going to be expanded.**

Donors

Living Donors. At present the best results come when kidneys are taken from carefully matched, closely related, living donors. Major ABO blood group compatibility is vital.[11] A sophisticated method of lymphocyte typing between the recipient and potential donors, developed by Terasaki,[12] has further increased the percentage of success.

Non-Living Donors. Unfortunately, about 75% of patients with renal failure do not have a suitable live donor available. In these cases, kidneys must be obtained from non-related donors dying unexpectedly of other causes. Patients with irreversible cardiac arrests, developing during or after cardiac surgery, have been used successfully. Occasionally, a patient may die in the operating room during an open heart procedure. Since adequate renal perfusion can be maintained with cardiopulmonary by-pass and pump oxygenation until potential recipients can be prepared, kidneys obtained from this source are particularly good. However, transplantation in such cases must be performed as an emergency, allowing selection of the recipient to be based only on ABO blood group matching.

If the potential donor has suffered a massive brain injury, death may be postponed by several hours, or even days, by artificial respiratory support. Such patients can be given fluids intravenously and mannitol to maintain good urinary output. Time permits the selection of the recipient from the patients being maintained on intermittent hemodialysis, based on leukocyte serotyping, as well as ABO blood group compatibility. Transplantation can then be carried out on a more elective basis, but only after death has been declared by the patient's attending physician and the family has agreed to organ donation.

Although matching is not as perfect with non-living donors, there are, nevertheless, some advantages. There is no risk to a living donor, and two kidneys can be obtained from a single donor; thus benefiting two recipients simultaneously (this has been done on 33 occasions to date at the Cleveland Clinic Hospital).

Legal Aspects. In most states the laws covering organ donation are outdated and inadequate, requiring permission of next of kin before transplantation can take place.[13] In 1967, a law was passed in the state of Ohio which gives any individual the right to dispose of his own organs as he himself wishes. It allows that right to take precedence over the wishes of any next of kin, and protects both physician and hospital from liability after transplantation has been performed in good faith.[14] It is hoped that similar legislation will soon be passed in other states, and as a result, more organs will become available for transplantation.

Transplantation

Logistics. Securing suitable non-living donors requires the close cooperation of all services in the hospital. When a patient is gravely ill a member of the renal transplantation team is notified, so that the suitability of the patient as a potential donor can be determined. In general, patients dying from neoplasms (other than brain tumors), septicemia, and known renal diseases have been excluded as donors. When in doubt, surgical exposure and examination of the kidneys has been performed in the operating room after permission has been obtained from next of kin.

The majority of non-living donors have died suddenly in the operating room, the emergency room, or in the intensive care unit (Table 1). Several kidneys have also been obtained from cooperating hospitals in Cleveland and in nearby communities. The method of obtaining and preparing the kidney for transplantation has been presented in another publication.[15]

Table 1

Primary Diseases of Cadaver Donors of Kidneys *

Coronary heart disease	33
Brain hemorrhage or tumor	28
Valvular heart disease	21
Aortic aneurysm	3
Chronic respiratory failure	2
Acute respiratory failure	1
Malignant lesion	1
Renal artery stenosis	1
Total	90

* Both kidneys were transplanted from 33 cadaver donors: nine kidneys were obtained from hospitals other than the Cleveland Clinic Hospital.

In many instances it is obvious at the time of

donor nephrectomy that the kidney is nonviable or anatomically unsuited for transplantation. Factors involved in accepting kidneys for transplantation have included: the type of death (sudden or after prolonged illness), the "warm ischemia time" (time from death until kidneys are perfused and cooled to 4 C), the gross appearance of the kidney, and the ease with which the kidney can be perfused. Histochemical techniques for assessing viability are currently being studied and show great promise. Results of these tests can be available soon after death, and appear to be a sensitive indicator of the viability of the kidney.[16]

There is still a tremendous need to make more kidneys available for transplantation. Since the "warm ischemia time" must be less than one hour, **speed is essential in the salvage of kidneys from non-living donors.**

Technique. The donor kidney is placed retroperitoneally in the iliac fossa of the recipient, as previously described.[17] In most cases the renal vein is anastomosed end-to-side into the external iliac vein, and the renal artery end-to-end into the hypogastric artery. If there is any question about the patency of the hypogastric artery, the renal artery may be placed into the external or common iliac artery, or even into the aorta. If the patient has had repeated dialyses via the femoral vein, the iliac vein may be partly thrombosed and should not be used. The opposite iliac vein or the inferior vena cava are preferable in this event.

The ureter is spatulated and implanted into the bladder by a submucosal tunneling technique.[18] Ureteroneocystostomy has been our procedure of choice because of a lower incidence of leakage (about 5%), and because ureteropyelostomy can then be performed as a secondary procedure to try and salvage the kidney if urinary extravasation occurs. It is interesting to note that the percentage of leakage is much higher when cadaver kidneys are used, and that in at least 50% of these there was evidence of definite rejection of the ureter.

Postoperative Care

Immunosuppression. In addition to the usual supportive measures utilized after any major abdominal surgery, all patients receive continuous immunosuppressive drug therapy postoperatively. Azathioprine (Imuran), in doses from 100 to 150 mg daily, and prednisone (Meticorten), 100 to 150 mg daily, are started immediately after surgery and continued in these dose ranges for at least one week. Thereafter, the dose is gradually tapered off to a daily maintenance of 25 to 150 mg of azathioprine and from 2.5 to 15 mg of prednisone, depending on the level of renal function and the presence of rejection or drug toxicity.

During the past year, antilymphocyte globulin (ALG) has been produced by injecting spleen cells into horses, as described by Iwasaki.[19] The technique has been modified to obtain an immunoglobulin fraction, which is less toxic and is now being given to all patients. The drug is given by intramuscular injection and is started several days prior to transplantation when living donors are employed, and on the day of operation in cadaver donor cases. The current dosage schedule is to administer ALG daily for two weeks after operation; then every other day for two weeks, twice a week for two more weeks, and then once a week for the final two weeks. By combining ALG with azathioprine, we have been able to reduce the dose of prednisone and, hopefully, will decrease the incidence of complications resulting from long-term steroid therapy.

ALG has been used in this fashion so far in 12 patients and, although five have died, rejection has not been a major factor. Eighteen other patients have received ALG as a secondary form of therapy for late rejection crises, and 12 of these patients are still alive with functioning kidneys. Serious anaphylactoid reactions have not yet been observed, and it is hoped that further use of this drug will improve the over-all survival rate.

Episodes of rejection not responding to the above therapy may be aborted by adding actinomycin C, 200 μg weekly, or by giving a short course of irradiation locally to the graft (150R every other day to a total dose of 600R).

Dialysis. After receiving a kidney from a non-living donor, many patients undergo a period of oliguria lasting from a few days to as long as two or three weeks before diuresis ensues and the homograft can maintain homeostasis. Intermittent hemodialysis is usually necessary to support life during this period; most patients require from two to four dialyses (Figure 1). Potassium exchange resin enemas may be necessary to help control hyperkalemia in the early postoperative period. As in any patient with oliguria, extreme care in maintaining fluid and electrolyte balance is important.

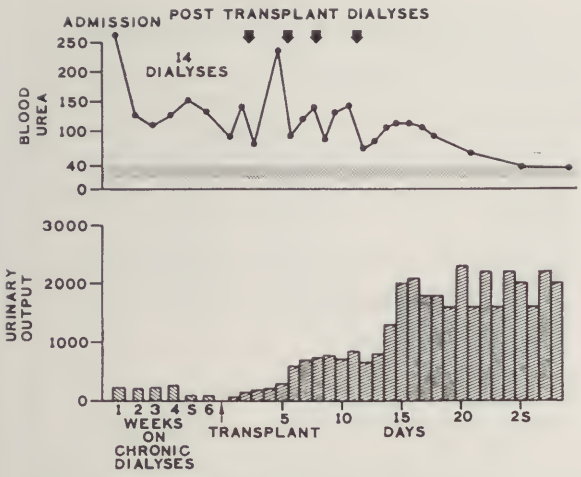

Figure 1. Graph showing postoperative course after cadaver renal homotransplantation, demonstrating transient oliguria.

Complications

The various causes of failure following transplantation are summarized in Table 2.

Table 2
Causes of Failure in Renal Transplants

Cause of Failure	Early (0-3 months)		Late (over 3 months)	
	CD	LD	CD	LD
Nonviable kidney	8	0	0	0
Urine leakage	5	2	1	0
Hemorrhage	5	0	0	0
Vascular complications	6	2	0	0
Rejection	10	4	9	5
Sepsis	3	3	0	0
Agranulocytosis	1	1	0	0
Total	38	12	10	5

CD = Cadaver (non-living) donor
LD = Live donor

Nonviable Kidney. Early in this series, selection of inappropriate cadaver donors led to the transplantation of a number of kidneys already beyond salvage. Postoperative *oliguria* often develops with cadaver kidneys because of the prolonged ischemia time. This may present a real problem in differential diagnosis, as the oliguria may be due to acute tubular necrosis, rejection, ureteral obstruction, or a problem with vascular anastomosis. The management of this problem has been discussed previously.[20]

Sepsis. Infection is a frequent complication and is difficult to differentiate from rejection and equally difficult to treat. It has been the direct cause of failure in six patients and has caused the death of 42 patients. In an attempt to avoid this complication, all patients are kept in reverse isolation during the immediate postoperative period; no drains are used, and the urethral catheter is removed from the bladder in the first 24 to 48 hours, unless the patient has gross hematuria complicating the situation.

Urinary Leakage. The sudden development of oliguria and a suprapubic mass is an ominous sign, and cystoscopy with retrograde pyelography, followed by prompt exploration, should always be considered in such cases. Early evacuation of urine, with secondary ureteroneopyelostomy (using the patient's own ureter or renal pelvis) can result in salvage of the kidney if infection can be prevented. Details of the urologic complications have been discussed in another report.[18]

Hemostasis is difficult to obtain in some recipients, as the bleeding may be a generalized capillary ooze. Administration of protamine sulfate intravenously, 25 to 75 mg during operation, and direct transfusion from a blood donor has been helpful in controlling this type of bleeding. A firm compression dressing is always used during the first 24 hours following operation to minimize hematoma formation around the graft.

Vascular Complications. Venous thrombosis has occurred in two patients. One had developed thrombosis of the iliac vein following multiple cannulization for hemodialysis, and in spite of thrombectomy, thrombosis occurred at the transplant site. In retrospect, it would have been better to use the inferior vena cava for renal vein anastomosis in this patient. A second patient had a simultaneous bilateral nephrectomy and renal transplantation performed, utilizing a non-living donor, and developed profound hypotension for the first 24 hours following operation. It is felt that simultaneous nephrectomy and transplantation as an emergency procedure may be too much for most patients, and this practice has been discontinued.

Massive thrombosis of both artery and vein, secondary to rejection, has occurred in four patients as a result of major ABO mismatching. This was done early in the series when cadaver kidneys were first being used, and this practice has also been discontinued. In one patient, the internal iliac artery thrombosed at the site of an endarterectomy performed to establish adequate blood

flow at the time of transplantation. End-to-side anastomosis into the common iliac artery is now employed in such cases, with less chance of thrombosis.

Rejection and Sepsis. Rejection reactions have been a major cause of failure, mostly in the early postoperative period, but also occurring as late as the second and third year after transplantation. Early recognition and aggressive immunosuppressive therapy is essential in the management of rejection crises. On the other hand, overly vigorous therapy may lead to excessive suppression of the patient's own defense mechanisms, ultimately leading to fatal sepsis. The combination of rejection and sepsis remains a deadly one in many patients, and better methods of immunosuppression are still needed.

Death. There have been 58 deaths among the 105 patients receiving non-living donor kidneys, and 22 deaths from the 47 patients receiving live donor kidneys since the program was started in 1963. The causes of death are summarized in Table 3.

Table 3
Causes of Death After Renal Transplantation

Cause of Death	Early (0-3 months)		Late (over 3 months)	
	CD	LD	CD	LD
Uremia	6	0	5	1
Sepsis	15	8	11	8
Pneumonia	2	0	6	0
Hepatitis	0	0	2	1
Cerebrovascular accident	4	0	1	1
Pulmonary embolus	0	1	1	0
Gastrointestinal hemorrhage	2	1	0	0
Necrosis of bowel	1	0	0	0
Myocardial infarct	0	0	1	1
Unknown	1	0	0	0
Total	31	10	27	12

CD = Cadaver (non-living) donor
LD = Live donor

Results

The over-all one year survival in patients receiving kidneys from related, live donors has been about 75%; patients receiving kidneys from unrelated, non-living donors has been 48%. Fortunately, most of the patients surviving one year have remained in good health for considerable time thereafter. Of 30 patients surviving over two years after transplantation, only five have subsequently died. There are currently 17 patients alive with functioning kidneys over three years, and four patients over four years in good health (see Table 4). The ultimate length of time that a transplanted kidney will survive is of course unknown, but the stability of function in those patients over three years after transplantation has been encouraging.

Table 4. Clinical Status and Length of Survival After Renal Transplantation

Clinical Status of Patients	Length of Survival Time After Transplantation (Years)									
	0-1		1-2		2-3		3-4		4-5	
	No. Patients		No. Patients		No. Patients		No. Patients		No. Patients	
	LD	CD	LD	CD	LD	CD	LD	CD	LD	CD
Excellent	0	4	0	0	2	1	2	3	2	1
Good	1	3	3	3	2	2	1	1	1	0
Fair	0	2	0	3	1	2	0	3	0	0
Poor	1	2	1	0	0	3	0	3	0	0
Total	2	11	4	6	5	8	3	10	3	1

It is gratifying to note the number of patients living and in good health over one year after transplantation. In addition to the patients listed above, 13 patients died between one and two years after transplantation (3 live donors and 10 cadaver donors); four patients died from two to three years after transplantation (no live donor, and 4 cadaver donors) and one patient (living donor) died between three and four years after transplantation. To date, no patient who has lived 4 years after transplantation has subsequently died.

The majority of patients dying over one year after transplantation have done so because of chronic rejection with complicating uremia or sepsis or both.

LD = Live donor
CD = Cadaver (non-living) donor

Patients who have lost a kidney have been placed back on hemodialysis, whenever possible, and considered for a second transplant.[21] To date 21 patients have been so treated, and results indicate that retransplantation may be successful up to 75% of the time, if the first kidney was lost because of technical problems. If the first kidney was lost because of rejection, however, the results are disappointing in general, and these patients are probably best managed by intermittent hemodialysis.

The Future

Immunosuppression. Although techniques of immunosuppression have been developed to a remarkable degree since 1960, further improvement is still needed. Conventional immunosuppressive therapy still cannot prevent rejection in many cases, and if it is pushed too far, the defense mechanisms of the patient are excessively suppressed and overwhelming sepsis ensues. The development of ALG has been of some help, but a superior drug is still needed.

Matching. Not only are better forms of histocompatibility testing necessary, but they need to be more rapidly performed and much more widely available. Tissue typing centers need to be set up in every major area engaged in organ transplantation, with central registries of prospective donors and recipients available to a number of cooperating institutions. In this way, any given donor can be rapidly matched against a large number of potential recipients, with the kidney ultimately going to that recipient most similar to the donor. With the use of computers and newer techniques of communication, it is conceivable that tissue typing could be effectively carried out on a state- or even nation-wide basis, allowing far greater selectivity and, therefore, much closer donor-recipient matching.

Organ Procurement and Preservation. The number of sudden deaths from cerebral and cardiovascular causes in this country far exceeds the number of potential kidney recipients. The majority of these kidneys are irretrievably lost, even though many patients and their families wish to make the kidneys available for donation. Since the kidney must be removed and perfused within one hour after death, it is often too late by the time the family and attending physician become fully aware of the possibility of organ donation. **Anticipation of the problem** in advance, with notification of transplant personnel on time, will make great many more kidneys available and, thus, minimize the tremendous stress and expense borne by recipients who must wait many months for a suitable kidney.

Organ recovery teams are already in existence in some areas, but must be increased both in number and in range. Two kidneys were obtained from a donor 75 miles from the Cleveland Clinic on Christmas Day 1967. The recovery team then transported both kidneys in a small hyperbaric oxygen tank in a police cruiser to the Cleveland Clinic, where simultaneous transplantation into two separate recipients was successfully carried out. Good liaison with the referring physician and with the state police made this possible. In the future, the use of air transportation should make organ transfer over long distances a practical reality.

Improved organ perfusion techniques are now being perfected;[22] it will soon be possible to bank kidneys in a pump-oxygenating machine long enough for tissue typing and viability testing. Optimal preparation of the recipient can then be carried out. Should the best patient for a given kidney reside in a distant locality, air transportation of the patient to the center processing the kidney should be entirely feasible.

Presented at the 13th Clinical Meeting of the Frederick A. Coller Surgical Society, September 28, 1967, New Orleans, Louisiana.

Renal Homotransplantation

PAUL BORMEL, MD
Baltimore, Maryland

I. Historic Background

Concept of transplantation in
Egypt—Sphinx
Greece, Rome—Human head; animal form
Pan
Centurion
Transplantation of leg of Ethiopian to saint
—St. Cosmos and St. Damian—painting by Fra Angelica—St. Marco's Museum, Florence, Italy—1400
Pedicle flap transplant to nose—Tagliocosa
—based upon poem "Sympathetic Slave"—1600
John Hunter—transplanted teeth—1771
Baronio—demonstrated free skin autografting in sheep—1804
Bauer—skin graft exchange between identical twins—1927
Medawar—demonstrated that lymph tissue recognizes and reacts against homologous tissue—1957

II. Terminology of Tissue Transplantation

Old Terminology	*New Terminology*	*Definition*
Autograft	Autograft	Graft in which donor is also recipient
Isograft	Isograft	Graft between individuals identical in histocompatibility antigens
Homograft	Allograft	Graft between genetically dissimilar members of the same species
Heterograft	Xenograft	Graft between species

* * * * *

HETEROTOPIC—A graft in different or unnatural recipient locations.

HOMOSTATIC or ALLOSTATIC—(Functional capacity of tissue)—Tissue from same species but deprived of viability, eg, arterial graft which serves a mechanical function but does not require viability.

HOMOVITAL or ALLOVITAL—Transplants expected to perform their full normal metabolic function after transfer.

ORTHOTOPIC—A graft of any genetic origin that is placed in the anatomical position normally occupied by such tissue.

III. First Successful Homotransplantation of the Human Kidney Between Identical Twins

BY: J. P. Merrill, MD; J. E. Murray, MD; J. H. Hartwell, MD; and W. R. Guild, MD. Peter Bent Brigham Hospital and Harvard Medical School; *JAMA* (**160:277** [January 28] 1956)

Identical Twins Used—(December, 1954)

Preliminary skin homografts were successful.

Blood typing (8 different tests alike).

Preliminary dialysis successful.

Site for transplantation: Disadvantages of renal fossa

a. Requires simultaneous nephrectomy, thus increasing the magnitude of the operation.

b. Necessity of a uretero-ureteral anastomosis with possible stricture formation because of the length of the transplanted ureter vascularized by the renal pedicle—too short to reach the bladder.

c. The upper thigh—site of previous transplants—Requires a skin ureterostomy with possible ascending infection and problems in urine collection.

Advantages of iliac fossa:

1. Allows for short ureteral segment directly into bladder.
2. Normal thermal environment.
3. Gravity drainage of renal pelvis and ureter approaches normal physiological conditions.
4. Easy accessibility to large vessels.

Operation began: 8:15 AM

Vessels prepared for anastomosis by 9:50 AM

Donor kidney brought to O. R.: 9:53 AM

Common iliac artery occluded: 9:53 AM

End-to-end anastomosis between free end of hypogastric artery and renal artery completed: 10:40 AM

End-to-side anastomosis between renal vein and common iliac vein completed: 11:15 AM

Total ischemia of donor kidney: 1 hr 22 min.

Entire kidney became turgid and pink immediately upon release of the arterial clamp.

Submucosal tunnel made for ureter in bladder—urine now flowing.

Total operating time: 3 hr 30 min. (December 23, 1954)

April 2, 1955—Left nephrectomy

June 20, 1955—Right nephrectomy—Because of persistent hypertension, pyuria, and fear of decrease in function to grafted kidney.

IV. Evaluation of the Status of a Graft

1. Clinical
   - — Fever, rapid pulse
   - — White count
   - — Pain
   - — Decline in status
2. Chemical
   - — BUN
   - — Creatinine
   - — Clearance
3. Angiography
4. Isotopes

V. Causes of Failure

1. Transplantation of a non-viable kidney
2. Sepsis
3. Urine leakage
4. Rejection
5. Hemorrhage
6. Thrombosis of the renal artery or vein or both.
7. Agranulocytosis
8. Forty-seven deaths among the 103 patients. In 31 instances, due to uremia or sepsis or both.

VI. Survival Data Selected from Analysis by Barnes of Cases in Kidney Transplant Registry

Donor	*Total Cases*	*Survival*	
		1 yr	*2 yr*
Mother (127), father (50)	177	53	32
Brother (54), sister (48), Other blood relative (12), Dizygotic twin (9)	123	54	52
Living, unrelated person	95	14	9
Cadaver	241	21	14

719 Renal transplants in 672 patients

VII. Technique of Preparation of Cadaver Kidney

Soon after death of the donor—200 mg of Na-Heparin and 500 ml of Mannitol given intravenously.

Artificial respiration and closed cardiac massage started and continued until kidney was removed.

The removed kidney is flushed with 250 ml of warm saline (room temperature), then with a special cold perfusate — 5 C. This rapidly cools kidney.

Kidney then kept cold to 10 C with isotonic saline.

Kidney kept in hyperbaric oxygen (3 atmospheres absolute).

Total ischemic time averages one hour.
("Use of Cadaver Donors," (*BJU* 38, 1966).

Data on Renal Transplants from Living (L) and Cadaver (C) Donors

Year	Number of Transplants		Functioning Grafts		Percentage of Total	
	L	C	L*	C*	L	C
1963	10	9	3 (5)	0 (2)	30	0
1964	5	22	3 (4)	8 (11)	40	36
1965	11	48	10 (7)	20 (24)	91	42
1966 (thru 1-6-66)	3	15	2	7	66	46
Total No. of transplants	29	94	17	35	59	38
Total No. of patients	25	78	17	35 +	68	45

* ( ) = Number of grafts that functioned for more than a six-month period.

\+ Four additional patients are alive without functioning kidneys.

Primary Disease of Cadaver Donors*

Disease	*No. of Patients*
Coronary heart disease	27
Brain hemorrhage or tumor	19
Valvular heart disease	17
Aortic aneurysm	3
Acute respiratory failure	2
Malignant neoplasm	1
Renal artery stenosis	1
Chronic respiratory failure	1
Total No.	71

*Both kidneys used from 23 cadaver donors. Six kidneys obtained from donors in other hospitals.

Causes of Failure in Renal Transplants*

Causes	Early: 3 months		Late: 3 months	
	LD	CD	LD	CD
Non-viable kidney	3	9	0	0
Sepsis	3	3	0	0
Urine Leakage	1	4	0	1
Rejection	2	7	2	6

Vascular disease	0	4	0	0
Agranulocytosis	0	2	0	0
Primary disease	0	0	1	0
Ureteral obstruction	0	0	0	1
Total	9	35	3	8

* LD, kidney from living donor; CD, kidney from cadaver donor
("Use of Cadaver Donors," *BJU*, 38, 1966).

VIII. Mechanism of Rejection

Kidney is transplanted between different animals or persons. (Homo- or Allotransplant)

It may initially function well for a week or more.

During this time, however, it gradually becomes infiltrated with lymphocytes and plasma cells, develops edema, and shows increasing degree of destruction of renal tubules.

Finally, the clinical features of rejection appear; the secretion of urine diminishes sharply and stops; the renal blood supply is reduced; and in the final phase of rejection, the kidney becomes totally infarcted.
Total time—usually 2 weeks.

General Methods of Treating Rejection Problem

1. Modify the antigenicity of the graft (has not been accomplished).
2. Suppression of recipient's response of immunity.
   a. Irradiation—whole body
      —local to fossa—1 week, 150r for 2 days for 4 treatments
      —to spleen or R.E. system
   b. Splenectomy
      Thymectomy
      Lymphadenectomy (local and distant)

c. Drugs—Type (1) to suppress immune response of recipient, eg, prednisone (100 to 300 mg daily)

d. Drugs—Type (2) which interfere with reaction of antibody with antigen and which reduce the mass of the lymphoid tissue.

1. *Azathioprine* (Imuran)—A derivative of 6-mercaptopurine. This depresses the immune response by acting as an antimetabolite which interferes with the synthesis of protein, including the formation of antibodies (1 to 3 mg/kg).
2. *Actinomycin* C (Catinomycin, Sanamycin)—Acts by attaching to portions of the DNA molecule, thus preventing formation of matching RNA molecule that is one step in the synthesis of protein by the cell (100 to 200 μg/kg, intravenously).
3. *Azaserine*—Inhibits the synthesis of nucleotides (only limited availability of drug).

Another Approach to Rejection Problem

To predict the degree of histocompatibility between donor recipient pairs—

—Leuko-agglutinins
—Lymphocytotoxins

Chronic Rejection

Chronic rejection of renal transplant occurs in a patient receiving immunosuppressive drugs, but treatment is not entirely effective.

Rejection occurs in a subacute manner with little in the way of edema or cellular infiltration.

Vascular lesions predominate which lead to:

(1) Cortical ischemia
(2) Tubular atrophy
(3) Interstitial fibrosis

Clinically—Nephrotic syndrome
Hypertension
Hyperlipemia

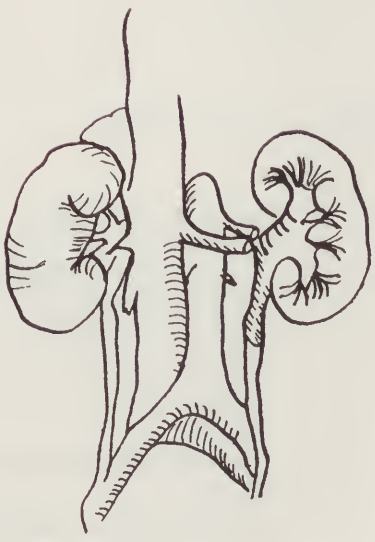
Increasing proteinuria means decreasing function.

IX. Problems

1. Rejection
2. Availability of donors
3. Legal
4. Organizational
5. Money

Ethical Problems in Renal Homotransplantation

1. Treatment is still at the experimental stage and is of debatable value.
2. Patient is submitted to a treatment which includes pain, inconvenience of major surgery, risks, and restrictions when the chance of restoring him to normal life is relatively small.
3. Dialysis versus transplantation.
4. Risks to donor: One Kidney
   Short Pedicle
   Post-op complications
5. Legal—Theological Law of Double Effect
   —English Common Law—Doctrine of Necessity



X. Comparison of Kidney Transplantation to Artificial Kidney

	Kidney Transplantation	*Artificial Kidney*
3-month survival	4 out of 5 persons alive	5 out of 5 persons alive
4-year life expectancy	2 out of 5 persons	5 out of 5 persons
Anemia	None	3 out of 5 persons
Hypertension	None	All
Neuropathy skin	None	Almost All
Local infection	None	Most
Diet	No restrictions	Restriction of salt and spices
General infection	Few	Most
Restrictions	Contact sports	Contact sports; dietary
Well-being	Few well	Most feel fatigued

XI. Future Prospects

Kidney Transplantation	Artificial Kidney
Perfect matching lymphocytes	Simplified apparatus
Improved storage	At home—overnight—automatic
Improved immunosuppression	Disposable—few dollars
Improved tolerance	No blood needed
More nation-wide centers	No risk of hepatitis
Heterotransplantation	Better membrane
Complete rehabilitation	Complete rehabilitation

vs DIALYSIS

Organic disease or dysfunction in the aged can often obscure the presence of mental or emotional disorder. The hostile or confused behavior of a geriatric patient who is hard of hearing, for example, is more likely to be attributed to his sensory deficiency than to underlying mental disorder. Consequently, many elderly persons who require psychiatrically oriented supervision and treatment are not receiving it.

The Management of Behavior Disorders in the Geriatric Patient

JOHN SPENCER, MD
Fairland Nursing Home
Silver Spring, Maryland

Nursing homes and related facilities are the cornerstone of extended care services and, as such, are designed for the aged patient who is too well for intensive hospital care, yet too ill to return home. These institutions provide nursing care and medical supervision to more than 700,000 elderly persons admitted ostensibly for physical illness.[1] However, as concluded by Stotsky [1] in his comprehensive review of nursing homes and their procedures, the mental health services of these facilities are not sufficient to cover the total needs of their residents. According to Goldfarb's findings,[2] for example, the vast majority of patients in nursing homes and homes for the aged may suffer significant mental impairment which,

for the most part, has gone unrecognized, and, as a result, untreated. The tendency, therefore, has been to substantially increase the availability of psychiatric services in these extended care facilities and to augment patient care beyond the basic provision of custodial management.

In line with this concept, patients at the Fairland Nursing Home in Silver Spring are offered an integrated course of somatic therapy and goal-directed activity programs such as, recreational, occupational, and physical therapy. With individualized medical and nursing care, such therapy can restore many elderly persons to functional capacities and can either delay or reverse the regressive tendencies in geriatrics who are seemingly beyond rehabilitation. Unfortunately, effective implementation of these rehabilitative programs is impeded for many patients because of their disturbed and often unmanageable behavior. Aggression, withdrawal, confusion or other types of disruptive behavior are overt manifestations of a patient's disturbed mental or emotional status. Psychoactive drug therapy, specifically with the phenothiazine compounds, is useful in controlling the behavioral manifestations of older aged patients.[3,4] We have found that thioridazine (Mellaril) is particularly effective in managing this type of geriatric patient, and the incidence of adverse effects is exceedingly low with this drug. The modulation of disruptive behavior obtained with thioridazine has helped to make patients amenable to the therapeutic programs established for them. As a result, the morale of nurses, attendants, and therapists who must work with these patients has been significantly improved.

The recognition and management of disruptive behavior problems in 65 patients (22 men and 43 women) is described in this report. The age range of these geriatrics was 56 to 95 years (median age was 79 years). They were admitted with various organic disorders (Table I), chief among them being arteriosclerotic, cerebrovascular, and heart disorders. Further evaluation suggested that these physical problems were exacerbated by emotional or mental disturbance. The patients exhibited mild to grossly disturbed behavior (Table II).

Treatment with thioridazine was instituted, with a starting dose (20 to 300 mg/day) individualized for each patient according to his needs. As a patient's behavior was stabilized, his dosage was adjusted to maintain optimal response. Although the maintenance dose also ranged from 20 to 300 mg/day, the majority of patients were both started and maintained on a dose of 20 to 100 mg/day. At the time data on these patients were collated for review, duration of treatment with thioridazine extended from less than one month to almost three years. A wide array of other drugs was employed in treatment, eg, analgesics, hypnotics, antibiotics, vasodilators, and cardiac glycosides. Intermittently during treatment with thioridazine, 18 of the 65 patients were also given antidepressants or other tranquilizers or both.

TABLE I

Diagnosis*

Diagnosis	No. of patients
Arteriosclerosis	27
Heart disease	8
Cerebrovascular Accident	6
Parkinson's disease	6
Hypertension	6
Arthritis	3
Diabetes	4
Hernia	3
Cystitis	3
Carcinoma	2
Blindness	2
Deafness	2
Organic brain syndrome	2
Pernicious anemia	2
Incontinence, Chronic prostatitis, Fracture, Herpes, Nephritis, Osteoporosis, Conjunctivitis, Hemiplegia, Emphysema, Asthma, Cerebral ischemia, Chronic brain syndrome, and Hyperthyroidism	1 each

* One or more in many patients; no medical diagnoses were made in eight patients.

TABLE II

Disruptive Behavior Symptomatology

Symptom +	No. of Patients *
Confusion	36
Agitation	18
Restlessness	15
Noisiness	11
Hostility	11
Uncooperative	10

* 25 patients were described as "senile."
+ More than one symptom in most patients.

Results

Tables III and IV show the results of treatment. Patients were categorized as demonstrating either "marked", "partial", or "no improvement", according to the extent of change in their behavior. "Marked improvement" was characterized

by substantial remission of target symptoms, notably, confusion, agitation, restlessness, and uncooperativeness. Of markedly improved patients the nursing staff noted they exhibited increased sociability and the capacity to cope better with their individual situations. Several judged to be "markedly improved" also tried to help the staff manage other patients. "Partial improvement" reflected relief from some symptoms or reduction of their severity, while other symptoms persisted. Generally, such patients became calmer and less difficult to manage as certain of their behavioral deviations were brought under control. The rating of "no improvement" was ascribed to patients who showed no progress or whose responses to treatment were obscure.

TABLE III

Results of Psychoactive Drug Therapy: Thioridazine Alone in 47 Patients

Results	Number of patients	Per cent of this group (47)
"Marked improvement"	21	45
"Partial improvement"	24	51
"No improvement"	2	4
Total	47	100

TABLE IV

Results of Psychoactive Drug Therapy: Thioridazine in Combination with Various Antidepressants and/or Tranquilizers in 18 patients

Results	Number of patients	Per cent of this group (18)
"Marked improvement"	8	44
"Partial improvement"	8	44
"No improvement"	2	12
Total	18	100

Of 47 patients treated with thioridazine alone (ie, no antidepressants or other tranquilizers), 21 were "markedly improved" after 1 month to 22 months of treatment. After 5 days to 35.5 months on thioridazine, 24 patients were "partially improved". Two showed "no improvement" following 4 days and 2.25 months of treatment, respectively.

Intermittently, 18 patients were given antidepressants or other tranquilizers or both in conjunction with thioridazine. Of these, eight showed "marked improvement" (after 3 weeks to 19.25 months on thioridazine), eight showed "partial improvement" (after 3 weeks to 11.5 months), and two showed "no improvement" (after 1 week and 5.5 months, respectively).

As shown in Tables III and IV, results were slightly better in patients treated with thioridazine alone ("marked improvement", 45%; "partial", 51%) than in those given adjunctive psychoactive medication ("marked" and "partial improvement", each 44%).

Discussion

Recognition of the need to improve upon the basic services of nursing homes and related facilities has prompted increased study of the psychotherapeutic approach in management of the aged.[1] In this approach, rehabilitation, through various programs of somatic therapy, psychotherapy, milieu therapy, and psychoactive drug therapy, is the broad objective. Among the phenothiazine compounds usually employed in such rehabilitative programs, thioridazine stands out as well tolerated and clinically effective in controlling the behavioral manifestations of emotional and mental disturbance in older aged patients.[4, 6]

Our findings are in general agreement with those of other investigators who found this drug useful in the treatment of disturbed geriatrics.[5-10] Of 65 patients exhibiting confused, agitated, restless, noisy, hostile, or uncooperative behavior, 16 were improved ("markedly" or "partially") and 2 were unaffected when thioridazine was administered with other psychoactive drugs; 45 were improved and 2 unchanged when treated with thioridazine alone. As target symptoms were alleviated, the patients became "more cheerful, sociable, and cooperative", appearing to adjust to their new environment with less difficulty. As a result, management was facilitated and the patients were better able to participate in coordinated rehabilitative activity programs.

The obvious benefits accruing from the use of thioridazine in our patients were further enhanced by the relatively low number of side effects observed with this drug. Tolerance of a drug is a

critical factor in geriatric treatment programs, especially with reference to phenothiazine-induced extrapyramidal side reactions. It has been estimated that at least "50% of all patients between 60 and 80 years of age receiving phenothiazine develop extrapyramidal side reactions." [4] Extrapyramidal reactions were not observed in our series of 65 patients who received thioridazine alone or in conjunction with a number of other drugs. Instances of drowsiness were transient and reversible with dosage adjustment. These findings are consonant with those of other clinicians who observed a decreased tendency toward adverse effects with thioridazine.[4, 9]

Since elderly patients routinely receive a wide range of medications at the same time, it was gratifying to note the compatibility of thioridazine when administered simultaneously. Similar findings were reported by Cavero.[10] In his series of geriatric patients, he observed no complications resulting from multiple drug treatment in conjunction with administration of thioridazine.

Summary

Disruptive behavior in 65 geriatric patients at the Fairland Nursing Home was substantially improved with the administration of thioridazine. This drug proved to be an effective adjunct in an integrated program of somatic and milieu therapy. Forty-seven patients were given thioridazine alone; marked improvement was seen in 21, partial in 24, and no change in 2. Of the remaining 18, given thioridazine with intermittent antidepressant or other tranquilizer therapy or both, 8 were judged to be markedly improved, 8 partially improved, and 2 unchanged. As confusion, agitation, and other behavioral manifestations were alleviated, these elderly patients were better able to function within the limitations of their physical and mental capabilities, and over-all management was facilitated. Thioridazine was compatible with a wide variety of chemotherapeutic agents administered to these patients primarily for concomitant physical disorders; no serious side effects were observed in any patient.

Preliminary Report on the Dietary Management of Patients With Advanced Carcinoma

Frequently, the main problem concerning patients with terminal types of carcinoma is anorexia, nausea, and vomiting. In an attempt to counteract these symptoms, the resulting malnutrition, and weight loss in three cases of carcinoma, the following diet was devised.

BARBARA A. SOLOMON, MD, MA
Baltimore, Maryland

Methods—Diet Descriptions

Fresh vegetables and fruit juices are given because they contain heat labile vitamin C, vitamin B1, and other minerals and vitamins in higher amounts than in cooked or canned fruits and vegetables.[1, 2] Also, juice is better than solid food, especially for patients with no teeth who find solid food difficult to consume. The Waring Juice Extractor (model VJ1) used in these studies was purchased by the American Cancer Society.

Eight to twelve ounces of juice a day are given —freshly made every day. The juice may be taken during multiple sittings or all at once, depending upon the ability of each patient.

Carrot juice is the main component of the diet because of its sweet taste and high vitamin A content. One package of carrots makes approximately 8 oz of juice. It is mixed with other fresh green vegetables. One half bunch of celery makes an additional 8 oz of juice. One bunch of parsley makes 1 to 2 oz; one half package of fresh spinach makes 4 to 6 oz; and one quarter head of cabbage makes 4 oz of additional juice. Other green leafy vegetables such as lettuce are also used. These vegetables are steamed four to eight minutes, only to tenderize. Potatoes and

corn are steamed 20 minutes for the same purpose.

The only protein foods used are eggs, cheese, nuts, and seafood, because these proteins are more tolerable in patients who are nauseated and prone to vomiting. The fat content of fish compared to meat makes it easier to digest. At the same time, fish is a complete protein and contains all 13 essential amino acids. The fish is boiled or baked.

The menus used may be classified into four diets. The first diet contains vegetable juices taken in quantities of 2 oz every one to two hours. Fresh fruit juices may be included or substituted here. This diet is only used for vomiting patients.

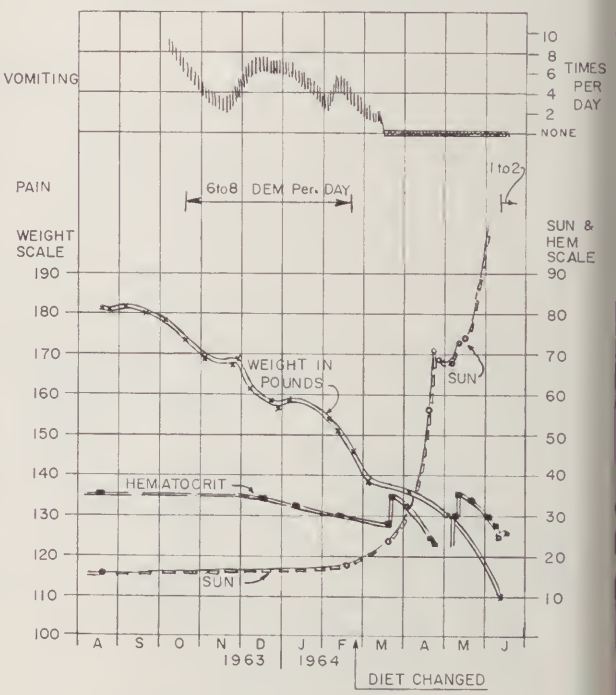
Diet II includes vegetable juices, eggs, and cereal. Soft boiled or poached eggs are given in the morning and cereal at noon or later.

Diet III is comprised of 4 oz of vegetable juice given three times a day between meals. Breakfast includes two eggs and cereal; supper includes mashed potatoes and fresh cooked vegetables which may be blended or puréed to increase tolerance.

Diet IV adds seafoods and salads to the diet. Breakfast includes fruit juice, cereal, or eggs, or both. Lunch contains a salad and a protein such as, yellow or cottage cheese, depending on the ability of the patient to tolerate fat. Fish, vegetables, and potatoes comprise the supper. The fish is baked or boiled. First, deep sea fish is added, then shrimp and crab. The vegetables are steamed. Mid-morning, mid-afternoon, and every evening 4 oz of fresh vegetable is taken. The juice is nutritionally superior to cooked vegetables, and is given in preference to cooked vegetables if there must be a choice.

Case I—47-year-old white female

Diagnosis: Adenocarcinoma of the colon was diagnosed in 1961 and a resection of the colon was done. In 1962, a second bowel resection was done to remove metastatic disease.



Symptoms: In August 1963, an expanding abdominal mass was noted. Nausea, vomiting, and weight loss were present. Constipation was present, requiring enemas twice a day.

Treatment: In March 1964, Diet I was begun. Two weeks later Diet II was begun; three weeks later Diet III was begun; five weeks later Diet IV was tolerated.

Results: Nausea and vomiting ceased in two weeks; pain abated. In February, she was using 8-50 mg meperidine a day. Pain medication was ceased in three weeks. In April there was no pain. The mass size had decreased to half the size at the time of death. The bowel function improved. In February 1964, she required two enemas a day. By June neither enemas nor suppositories were required. Weight loss decreased. Two months prior to diet change the weight loss was 20 lb. The weight loss two months subsequent to the diet change was 8 lb.

Follow-Up: Uremia was noted ten weeks after the new diet was instituted. The patient was comfortable until death with no nausea, vomiting, or pain. She died in a coma. Autopsy showed adenocarcinoma of the sigmoid, recurrent with local pelvic extension and metastasis to the brain, lungs, liver, diaphragm, peritoneal serosa, uterus, regional lymph nodes, chronic pyelonephritis, arteriolar and arteriolonephrosclerosis, and bilateral ureteral obstruction due to pelvic tumor extension.

Graphic Representation of Case I

Case II—57-year-old white male

Diagnosis: He developed a left neck mass in April 1964. A transitional cell carcinoma was

diagnosed on biopsy. He received three courses of local radiation to the neck area. A primary site was not found.

Symptoms: Anorexia and weight loss occurred. He was 5 feet, 11 inches tall. His weight was 150 lb at the time of the diet change. There was beginning ulceration beneath the left mandible. The dietary regimen was started in October 1965. Diet IV was begun as the patient was able to tolerate this from the start.

Results: The weight loss continued, but at a decelerated rate. The appetite improved, and he was able to eat in greater quantities for five and one half months. The ulceration continued to get worse until December 1965. Then, his strength improved. After this time, the ulceration remained approximately the same until the time of death in April 1966.

Follow-Up: March 1966 he suddenly experienced severe dysphagia, and was admitted to Baltimore City Hospitals where a gastrostomy was contemplated but not done. The patient was maintained on fluids given intravenously, and died April 7, 1966 in respiratory distress.

Autopsy: Microscopic review revealed a poorly differentiated squamous carcinoma invading the left upper neck and left oropharynx. A primary site could not be determined. There was no distant metastasis. The esophagus admitted only the tip of the small finger and, microscopically, revealed fibrous reaction due to radiation. The lungs revealed severe necrotizing bronchopneumonia.

Case III—55-year-old white female

Diagnosis: Adenocarcinoma of the colon with metastasis.

Symptoms: Nausea, vomiting, weight loss, abdominal pain, and constipation occurred. The diet was changed. She was given Diet I for ten days; diet II for four days; diet III for three days; and then diet IV was given.

Results: Subsequently, the nausea and vomiting ceased. The abdominal mass reduced in size, and the abdominal pain was reduced.

Follow-Up: Six weeks after the new regimen was begun, the patient became aware of her diagnosis. She refused all food and medication. In a few weeks she lost 50 pounds and died.

Autopsy: No autopsy was obtained.

Discussion

Cases I and III with carcinoma of the colon will be discussed together because of the similarity in diagnosis. The nausea and vomiting stopped in Cases I and III. The explanation of this interesting effect is not clear. Pain decreased and ceased in one month in Case I, and decreased in Case III. The size of the abdominal mass decreased in both these patients. The explanation for these last two effects is also unknown. In Case II, weight loss decreased probably because his appetite improved and he assimilated more food. His strength also improved, possibly, for the same reason. The improvement in appetite may or may not have been due to improved vitamin B or other vitamin combination intake.

Summary

A dietary regimen which is nutritionally superior and more suited to the needs of patients with terminal carcinoma, in that it is liquid and better tolerated, is presented. It also may make this type of patient more comfortable and stronger for a given period of time. A more intensive and controlled study would be necessary to determine if length of life could actually be prolonged.

Sarcoma Botryoides

H. MELVIN RADMAN, MD
Baltimore, Maryland

Several years ago, unusual findings were reported in a patient with a huge abdominal mass. It was thought that the tumor was not associated with disease of the genital system, but rather represented an example of primary omental sarcoma. Most authorities would agree that an accurate clinical or pathological diagnosis is difficult in such an entity. Subsequent events proved the validity of this contention.

From time to time, diseases that produce abdominal or pelvic masses have been confused with gastrointestinal maladies, pelvic bone, or urinary tract pathology. Conversely, it has been shown that entities which produce signs not referable to the genitalia are, in reality, diseases of the uterus, tubes, or ovaries. The following data is such an example. With the expulsion of a polypoid mass which proved to be similar, histologically, to the abdominal masses, it would appear that the over-all picture of the disease in this patient was that of a mixed mesodermal tumor. At first, the lesion in the peritoneal cavity seemed to be primary, but later was found to be the secondary extension of a uterine tumor that had not yet been discovered. Lebowich and Ehrlich,[1] with an exact standard of classification, believe that heterologous tumors are rare, and should be reported whenever encountered.

Morehead and Bowman [2] state that those tumors are not uncommon; they contend that a thorough examination of each specimen would yield more examples. An analysis of the literature concurs with the former opinion, as there are only 295 cases reported to date.[1-11]

The factors that make this case presentation of interest are (1) The appearance of what proved to be a secondary lesion as an apparent primary abdominal mass; (2) The lack of genital signs and symptoms that would lead one to believe that the disease was, in reality, of the uterus; (3) The survival of the patient for three years without other gross evidence of extension, invasion, or metastases; and (4) The addition of another case of mesenchymal tumor to the literature.

Case Report

Mrs. S. G., a 32-year-old white woman, sought medical advice because she noticed a progressive enlargement of her abdomen. This was associated with lower abdominal pain. The symptoms seemed to be more marked in the last months. The patient had been married about three or four weeks; she denied the possibility of a pregnancy. Her menses had begun at 14 years of age, appeared every 28 days and lasted four days. There was no history of amenorrhea, metrorrhagia, or menorrhagia. There were no associated gastrointestinal symptoms, but she did have occasional episodes of frequency of urination. She was aware of the mass in her abdomen, and felt that it had become progressively larger. The family and past histories were irrelevant. However, one sister had had a hysterectomy for fibroids several years ago. The general physical examination revealed a well-nourished white woman, not in acute distress. The secondary sex characteristics were well developed. There were no positive somatic findings, except for the mass in the abdomen. This mass was hard, regular in outline, and appeared to arise from the pelvis. The tumor seemed to be mobile, was not tender to the touch, and extended to the level of the umbilicus. Fetal heart tones were not heard, and fetal movements could not be elicited. A pelvic examination revealed a marital outlet. Bartholin's gland, Skene's duct, and urethra had no abnormalities. There was no cystocele, rectocele, or prolapse. The cervix was clean and appeared to be nulliparous. The abdominal mass palpated previously seemed to arise from the pelvis and, apparently, was continuous with the uterus which could not be felt separately. There was some slight fullness in the cul-de-sac but no palpable pathology in either adnexal region. Despite the lack of signs or symptoms of pregnancy, a radiological examination of the abdomen was done. This failed to show evidence of a fetal skeleton or any areas of calcification. Both psoas muscles and kidneys were not well demonstrated because of the soft tissue shadow produced by the mass. The radiological report stated that there was a large mass present of undetermined origin. The cytological smears revealed no evidence of malignancy. The hemogram showed 11.3 gm of blood, or 78.0% hemoglobin, and 38 ml of blood hematocrit. The erythrocyte count was 4,210,000 per cu mm. There were no other significant findings.

The preoperative diagnosis was multiple myoma of the uterus. Under a general anesthetic, the abdomen was explored through a low transverse muscle cutting incision. Upon entering the peritoneal cavity, a single large tumor was found lying free and unattached, save by multiple omental vessels. The uterus, tubes, and ovaries were normal in size and contour. There were no other pathological lesions in the pelvis, and no evidence of tumors of the uterus. The omental attachments of the tumor were doubly ligated, and the large mass was removed without difficulty. Further exploration of the abdominal and pelvic viscera failed to reveal significant findings. The patient's postoperative course was uneventful. She was discharged on the eighth postoperative day.

The surgical pathological report of the specimen removed was as follows. The specimen consisted of a flat, lobulated, yellowish white tumor weighing 1,950 gm. It measured 20.0 x 18.0 x 8.0 cm. The surface was covered by dilated blood vessels. The mass was firm in consistency. On section the cut surface was homogenous, yellow-white-pink in color, and fleshy of rather hard consistency. Microscopic section revealed the typical whorl-like appearance of a myoma with areas of degeneration. Final diagnosis was degenerating parasitic fibromyoma.

The patient re-entered the hospital on November 14 with a complaint of lump in the abdomen of one month's duration. She was then 33 years of age and married for one year. Following her initial operation she was seen on January 4, 11, March 24, June 22, September 21, and October 5, 1961. On each occasion the pelvic examination revealed no palpable pathological findings in either the tubes, ovaries, or uterus. On October 20, 1961, she complained of abdominal pain. There was some fullness in the left adnexal region; none on the right. She was thought to have pelvic inflammatory disease and, therefore, was given antibiotics for four days. The symptoms and the fullness in the fornix disappeared. However, on November 3, 1961, the patient again complained of pain in the abdomen. The menses were still regular. The last period occurred October 29, 1961. There was no other relevant information. The general somatic examination revealed no positive findings. Palpation of the abdomen revealed that the liver, spleen, and kidneys could not be felt. There was a well-healed transverse scar in the lower abdomen, and an irregular hard and somewhat fixed mass extending from the pelvis to the level of the umbilicus. The pelvic examina-

tion revealed a marital outlet. The Bartholin's gland, Skene's duct, and urethra revealed no abnormalities. There was no cystocele, rectocele, or prolapse. By vaginal examination, a mass was found closely adherent to the uterus. The mass seemed to be more developed on the left than on the right, and continuous with that felt in the abdomen. The rectovaginal examination gave no additional information.

On November 15, 1961, under general anesthesia, the abdomen was opened through the previous transverse scar. Multiple firm masses with blood supply from the omentum were encountered. The vessels were clamped and the tumors removed. Areas of the bowel, particularly many of the appendices epiploicae, were involved in the disease process. The pelvic cavity showed no evidence of disease or abnormality of the uterus, tubes, or ovaries. The postoperative course was uneventful. She was discharged from the hospital within one week.

The surgical pathological report on the first tumor was that of a parasitic fibroid. However, as the findings unfolded, it became apparent that the original diagnosis was misleading. A re-evaluation of the microscopic sections showed some evidence of what now is interpreted as mitotic activity compatible with sarcoma. The surgical pathological report of the second specimen revealed: two specimens labeled multiple tumors attached to peritoneal surfaces, multiple peritoneal tumors and scar tissue. The first specimen consisted of four large rounded tumors measuring 6.0 cm, 7.0 cm, 9.5 cm, 5.0 cm in diameter and weighing together 1150 gm. All four tumors were firm in consistency, covered by a smooth, yellowish-pink, translucent capsule. On section, three of the tumors revealed a uniform yellowish-tan, shiny, slippery cut surface. The fourth one showed a slight brownish discoloration in the center and it was slightly firmer in consistency. The second specimen consisted of eight additional tumors measuring 1.5 to 3.0 cm in diameter, but otherwise identical to the previously described tumors. Diagnosis: Multiple tumors attached to peritoneal surfaces; all show a similar appearance, that of sarcomata, with one showing extensive necrosis.

For the first three months following the second operation, the patient received 2320 R cobalt 60 teletherapy over the anterior and posterior pelvis, anterior upper and lower abdomen, and the posterior upper and lower abdomen. In the ensuing 14 months, there were no palpable abdominal or pelvic masses. She felt well, gained weight, and had no complaints. Fifteen months after the operation, she again developed lower abdominal and pelvic masses. A few months later, she complained of a protrusion from the vagina, and expelled a large polypoid mass without bleeding or pain. The surgical pathological report of this tissue revealed: a polypoid cellular tumor containing many newly formed vascular spaces, many of these filled with blood. There was some myxoid tissue present and a few endometrial glands. The cells had ovoid or spindle-shaped nuclei, and a few were anaplastic. The tumor appeared to rise from mesodermal tissue. The diagnosis was Botryoid Sarcoma.

Comment

After the patient developed additional abdominal masses and a second operation was done to remove them, it became apparent that the original tumor was not a parasitic fibroid. The most common conditions of the omentum such as, mesenteric cyst, inflammatory tumors, torsion or traumatic injuries had to be considered. However, the recurrence and extension, as well as the microscopic evidence of the tissues removed at both operations, led to the diagnosis of sarcoma. For two years in which the patient was followed, there was no symptomatology to the genitalia. In addition, a thorough exploration of the pelvic organs had been made at each laparotomy, and no evidence could be detected of uterine, tubal, or ovarian involvement. Therefore, the tumor masses were assumed to arise as a primary lesion from the omentum.

According to McDonald's criterion, it was believed that the abdominal mass found in this patient represented one in less than 100 reported examples of primary omental sarcoma.[12] In 1927, he stipulated a set of circumstances whereby a patient with an abdominal mass could be considered suffering from a primary omental malignancy. Those specifics consisted of (1) No evidence of disease elsewhere in the body; (2) The removed tissue must show microscopic evidence of malignancy; and (3) There must be recurrence, extension, or metastases.

When the polypoid mass was expelled from the vagina, the requirements were nullified. The surgical pathological examination of the growth revealed elements of a mixed mesodermal tumor, and, thus, the true nature of the disease was real-

ized. The clinical course of the patient substantiates Wills' theory concerning primary tumors, ie, that a growth must not be considered primary unless there is complete evidence that it did not arise from an unsuspected tumor elsewhere.[13]

Although there are approximately 300 examples of mixed mesodermal tumors in literature, most authors consider them to be rare. Herbut classifies them in three groups dependent on location.[14] In early childhood, they may originate in the vagina. They are seen to arise from the cervix, in active sex life. While in the menopause, the usual site is the body of the uterus. There have been occasions when the cervical growth has been observed in the menopausal woman. Similarly, the corporeal growth has been found in the active menstrual life.

The unusual train of events in this case history is of interest. It would not have been logical to remove the uterus, tubes, or ovaries at either operation since there was no evidence at first that the disease originated in those organs. Sarcomatous lesions notoriously mestastasize primarily by hematologic spread and, secondarily, by the lymph channels and by direct invasion. The vast interchange of blood through the vessels between the uterus and adjacent viscera and peritoneum is well known. The interchange might account for the appearance of a large metastatic tumor before the discovery of the primary lesion. Otherwise, the appearance of a secondary lesion as a primary finding remains unexplained.

As an area of special interest, pediatric surgery has developed primarily for two reasons. The first of these is the unique nature of congenital anomalies which occur in the newborn infant and which, if not recognized and immediately treated, will result in death of the baby, or a severely debilitated child. The second reason has been a gradual realization that the physiological responses of a baby are quantitatively and qualitatively different from an adult and that dramatic changes can occur with greater rapidity during the operative and postoperative care of an infant. It seems reasonable, therefore, that an extended experience with these problems is essential for proper surgical care of an infant. We propose to focus attention upon the second of these two general problems, namely the quantitative and qualitative management of the postoperative infant.

Postoperative Management of Infants

J. ALEX HALLER, MD
Robert Garrett Professor of Pediatric Surgery
Division of Pediatric Surgery
Department of Surgery
The Johns Hopkins Hospital and
University School of Medicine

Postoperative Care

Postoperative care of the infant presents the single greatest challenge in pediatric surgery, for the margin of error is small, and without reliable monitors, may be easily exceeded. Lability has been cited as an outstanding characteristic of the response of infants to stress and trauma. For this reason potential dangers are constantly present, are varied in number, and, therefore, invite the development of specialized techniques for their management. This potential for rapid change requires that the utmost vigilance be exerted to detect subtle signs that may indicate more serious alterations in an infant's condition.

All patients who are admitted to our infant Intensive Care Unit in The Johns Hopkins Hospital are followed on fluid and electrolyte flow sheets with balance calculations every six hours or less. The important features of this flow sheet are serial measurements of central venous pressure, total serum solids, hematocrit, urinary specific gravity, and serum electrolytes, together with precise recording of all fluid intake and output and daily body weights. An infant's vital signs and clinical response remain the most important criteria of satisfactory maintenance of homeostasis.

Our monitoring routine in infants is shown in Table I. It will be noted that this gives a continuous picture of the patient's condition and documents any serial changes which may occur. Since none of these observations requires elaborate equipment, they should all be readily accessible to all physicians, especially in an intensive care area. When coupled with the determinations of serum electrolytes, they offer a very precise guide to therapy.

TABLE I

MONITORING ROUTINE IN CHILDREN

	Central venous pressure
	Total serum solids
q 6 hr	Hematocrit
	Urine specific gravity
	Intake
	Output
Daily	Body weight
	Serum electrolytes & urea N_2

Urinary Output

In older children, urinary output is usually a reliable index of intravascular volume and renal perfusion, but in the newborn infant, both volume and specific gravity of the urine may be misleading. A newborn infant, and especially a premature infant, is limited in his ability to increase volume and to concentrate urine. Urinary specific gravity in this age group may, therefore, remain low in spite of serious, inadequate water intake. On the other hand, congestive failure may develop with overhydration since a relatively low glomerular filtration rate may limit the renal response in such situations and not be immediately detected. Urinary output, then, is a very valuable index of adequate intravascular volume and hydration only of serial determinations are carefully recorded and the limitations of the immature kidney recognized.

Central Venous Pressure

We have found a serial determination of the central venous pressure the single most helpful measure of homeostasis in the postoperative infant. The value of central venous pressure as a reflection of an adequate functional blood volume has been widely recognized. Many standardized techniques have been developed and are important additions to the regimen of postoperative care in older children and adults. It is somewhat strange, therefore, that adaptation of techniques for central venous pressure measurement in neonatal surgery has remained limited. This has been due primarily to technical restrictions imposed by tiny structures. The threats of overhydration and excessive transfusion, ever-present dangers in a tiny infant, are greatly minimized with serial observations of central venous pressure.

In the absence of cardio-respiratory problems, serial central venous pressure determination is a direct reflection of effective cardiac filling. Under these circumstances, it is safe to assume that a decreased central venous pressure is indicative of an inadequate central blood volume, but if the central venous pressure is normal, some other cause must be found for inadequate cardiac output and peripheral perfusion.

The insertion of a catheter for central venous pressure determinations may appear difficult in the newborn infant because of a scarcity of satisfactory sites for its insertion. It must be emphasized that the catheter tip must lie in the central venous pool if it is to reflect accurately the filling pressure of the right heart. The most common site for the insertion of a peripheral venous catheter, the sapheno-femoral junction at the groin, has been shown to be a poor choice for the insertion of a central venous monitoring catheter. Although the reliability of the inferior vena caval pressure as an indicator of effective cardiac filling has been questioned, recent experimental work would suggest that it is accurate as long as the intra-abdominal pressure remains normal. Many operative procedures require abdominal exploration, and many infants in the postoperative period become moderately to severely distended. Because of this concern about the changing intra-abdominal pressure, studies were initiated in our laboratories to evaluate the significance of these clinical observations and concerns. As shown in Figure I, when the intra-abdominal pressure was elevated by instilling air under pressure, the inferior vena caval pressure, measured through an inlying catheter, rose concomitantly, but a similar monitoring catheter in the superior vena cava continued to measure the normal central venous pressure. In every instance any increase in intra-abdominal pressure was reflected immediately by a corresponding rise in inferior caval pressure, while in no instance was there an associated fluctuation in superior caval pressure. These experimental observations have been extensively substantiated in a number of clinical situations. It, therefore, seems certain that any degree of abdominal distention will interfere with accurate estimations of central venous pressure via the inferior vena cava.[1]

It has proven technically difficult to insert a small catheter through the antecubital fossa into the superior vena cava and has proven to be difficult to insert a catheter directly beneath the clavicle into the subclavian vein without producing a pneumothorax in the infant. Therefore, these otherwise satisfactory adult techniques have been abandoned, and a technique for cannulation of the jugular vein has been standardized in our surgical unit.

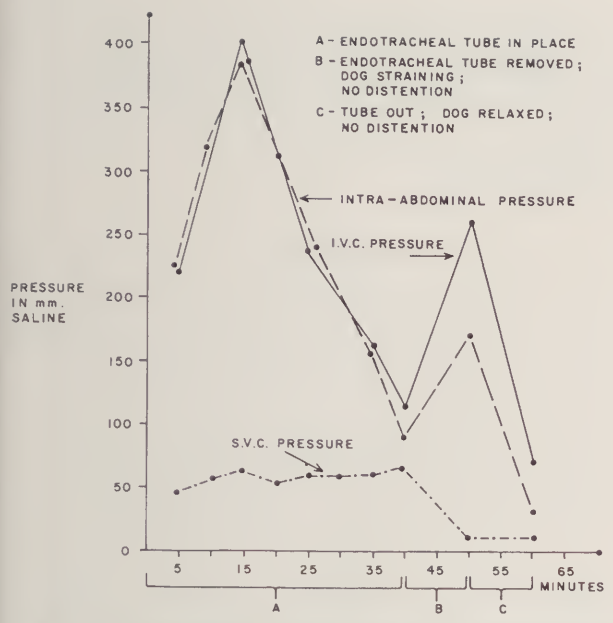

Fig. 1. Relationship of inferior vena caval (IVC) and superior vena caval (SVC) pressures to alterations in intra-abdominal pressure.[1]

The external jugular vein is readily accessible and is usually of sufficient caliber to allow insertion of a suitable Silastic catheter. The presence of a cannula in the neck of an infant offers no hindrance either to his movement or to his management. Rarely have we found it necessary to use the internal jugular vein in the very small premature infant. Cannulation of the internal jugular vein is not a procedure for the inexperienced and should only be used when other routes are not adequate.

A large Silastic catheter may be introduced into the central venous pool using a cutdown technique over the external jugular vein of the infant. Although air embolization might be considered a potential hazard, none has been encountered. Silastic tubing has been employed as catheter material since it diminishes the risk of thrombosis and allows prolonged use. A constant infusion pump, such as the Harvard unit, allows administration of small, precise quantities of parenteral fluids over long periods. The other significantly valuable aspect of central venous catheterization is that it constitutes a dependable means of serial sampling of venous blood. It this way, blood electrolyte and blood gas determinations can be carried out at indicated intervals without venipuncture or capillary sticks.

Normal values for right atrial and central venous pressure are the same in the infant as in the adult, although there are some increases in fluctuations associated with infant respiration and crying. The most important concept in central venous pressure monitoring is that the over-all trend in serial determinations of the pressure, rather than any isolated observation, is the critical factor in judging response to treatment. We have described in detail a satisfactory technique for establishing a central venous pressure monitoring setup in infants.[2]

Determination of Total Serum Solids

The total serum protein content and concentration is an accurate reflection of the relative state of hydration and the level of serum proteins. This measurement is particularly useful in situations associated with massive fluid and protein losses, as for example, in burns or in the postoperative period when there has been extensive soft tissue injury. When this determination is combined with urinary output and a careful measurement of fluid intake, a very precise assessment of intravascular concentrations is available.

With the introduction of a small accurate hand refractometer, an index of total serum solids can be determined from two small micro-hematocrit tubes. The measurement of total serum solids, coupled with simultaneous determinations of hematocrit and venous pressure, provides considerable insight into whether the patient requires water, plasma, or blood replacement at any particular moment. Such data are particularly valuable when one is uncertain whether oliguria, which so often follows trauma and surgery, is due to primary renal damage or to inadequate fluid replacement.

Temperature Regulation

The thermal regulatory mechanism in premature infants is notoriously unstable, but the same is true of the full term infant and the postoperative newborn. Great care must be taken to monitor temperatures serially, either with esophageal or rectal thermistor probes, or with surface temperature sensors. Prolonged exposure in the air-conditioned operating room and the additional hazard of massive fluid replacement by cold blood or plasma add to this problem of temperature control. It is imperative that all solutions be warmed prior to administration if by no other means than

by coiling a plastic intravenous tubing in a container of warm water, the temperature of which should not exceed 110° F. Highly volatile prep solutions in the operating room should be avoided, and every infant should be placed on a circulating warm water blanket during the operative procedure. The controlled environment of the familiar isolette in the postoperative period is an ideal means of sustaining both warmth and humidity. Theoretically, the most accurate measure of infant temperature is achieved from surface temperature sensors, because the surface temperature loss is most directly related to caloric losses. However, the time-honored rectal thermometer is a very satisfactory monitor in the postoperative period.

Acid Base Balance

The importance of monitoring acid base balance is greatly increased during the following extensive surgical procedures such as, thoracic and cardiovascular operations. Metabolic acidosis is very commonly associated with rather short periods of inadequate cardiac output as a result of myocardial depression or with the use of certain open heart surgical techniques. The resulting metabolic acidosis is further increased with the infusion of stored blood that has a low pH. Administration of small quantities of sodium bicarbonate or, in more serious situations, some of the artificial buffering systems, such as Tris buffer, may be useful in the management of a serious imbalance.

Circulatory

Small bedside electrocardiographic monitors are especially helpful in the postoperative management of an ill infant. This is used primarily to record any significant changes in heart rate or rhythm, rather than as a means of studying myocardial electrical activity. After the more complex cardiac procedures an intra-arterial pressure recorder may be quite useful, especially if there is transient myocardial depression and peripheral vascular instability. Under these circumstances, careful monitoring of the intravascular pressure is a good index of cardiac output.

Respiratory

If short term respiratory support is necessary in the postoperative period, a plastic endotracheal tube may be used. For prolonged respiratory support and especially when respirators of a positive pressure type are necessary, we have been dissatisfied with prolonged tracheal intubation. With the introduction of a new solid Silastic tracheostomy tube which obviates the potential hazards of the metal tube in the infant's trachea, we are much happier about our results with the use of tracheostomies in infants. We have found the Silastic tracheostomy tube particularly useful when respirator support is necessary, as it completely frees the head and nasopharynx from intubation and makes for easier management and fewer complications of the upper airway.

Gastrointestinal

Following any extensive intra-abdominal operative procedure, a gastrostomy should be seriously considered as an important form of postoperative management. This is especially true in the newborn infant where prolonged nasogastric intubation is so frequently complicated by otitis media and upper airway obstruction. A simple Stamm type gastrostomy requires very little additional operative time and constitutes a superb means of immediate postoperative decompression of the gastrointestinal tract and an ideal way in which to begin early alimentation.

your medical faculty at work

by John Sargeant
Executive Secretary

The Executive Committee met on Thursday, March 20, 1969, and took the following actions:

1. Authorized preparation and dispatch of a letter to the members of the Baltimore City Medical Society in response to one mailed by the Baltimore City Medical Society President that was considered "inflammatory and erroneous."
2. Authorized expenditure of funds by the Traffic Safety Subcommittee for material dealing with legislative activity in connection with Implied Consent or Express Consent legislation.
3. Authorized expenditure of funds for expenses of two Delegates from The Johns Hopkins Medical School Student American Medical Association Chapter to attend the annual meeting of the national organization.

The Council met on Thursday, March 20, 1969, and took the following actions:

1. Authorized the Chairman to recommend to the House of Delegates the disbandment of the PL 89-97 Liaison Subcommittee appointed by the House in April 1966.
2. Voted to recommend to the House that Emeritus Membership be granted to various individuals on the recommendation of their component societies; and that honorary membership be granted to one individual on the recommendation of the Talbot County Medical Society.
3. Ratified legal defense for various physicians who were eligible; and denied the same defense to one physician who had not paid his dues before January 31 in the year in which the alleged offense occurred.
4. Heard that one case had been closed with a "modest settlement".
5. Heard various purposes for which Educational Funds had been expended throughout the state in hospitals; and referred to the Mediation Committee an amount on one hospital statement in order to ensure that a violation of medical ethics is not occurring.
6. Approved the 1972 Annual Meeting dates as April 5, 6, and 7.
7. Tabled until the June Council Meeting, the question of approval of a proposed Hearing and Vision Screening Program for preschool children.
8. Approved the recommendation of the Policy and Planning Committee that a photograph-portrait of all living past presidents be developed, as well as incoming presidents.
9. Adopted an addition to the Joint Statement on the Role of the Registered Nurse in the Care of the Patient with Cardiovascular Diseases in Coronary and Intensive Care Units as follows:

   "While standing orders may be established, it is essential that the orders applicable to each patient be included in that patient's chart and signed by the attending physician."

10. Declined to approve an addendum to the Physician Guidelines for the Performance of Therapeutic Abortions, which was recommended and reads as follows:

    "Continuation of a pregnancy in a fifteen-year-old or under may represent a grave impairment to the mental health of the mother and, therefore, warrants an evaluation for the possibility of a therapeutic abortion."

11. Adopted as policy that Committees and Subcommittees of the Faculty should not make direct approaches in any official capacity to General Assembly Representatives nor establish policy in connection with Faculty positions on legislation without prior clearance.

12. Declined to appropriate funds for testimonial scrolls to Nursing Associations complimenting them on the services provided to the public.
13. Authorized disposal of the large table in the library and its replacement with individual carrels, subject to approval and evaluation of the table's value by a qualified person.
14. Expressed its appreciation to the staff and Legislative Committee in connection with legislative activity during the 1969 General Assembly.
15. Asked the President to request a report from the Ad Hoc Committee on Tuberculosis Care, authorized by the Council at the January 1969 Council Meeting.

The Executive Committee met on April 3, 1969, and took the following actions:

1. Discussed with representatives of the Social Security Administration at Woodlawn the current Tuberculosis Screening Project in progress. The Faculty had some reservations about the wording of the letters being sent to the patient and his physician, as well as other aspects of the letters.

   It was agreed that the Faculty would make suggestions for improvements in these, and also, that Social Security Officials be encouraged to discuss these projects in advance so as to secure the cooperation of the individual physician and his organization. The Social Security Officials agreed to these suggestions.
2. Agreed to recommend to the Council's June 1969 meeting that the Faculty decline to approve of the proposed state-wide Glaucoma Screening Project as proposed by the State Health Department. This was recommended because prior approval has not been obtained by the organization providing the screening population.
3. Approved the proposal of the Maryland Tuberculosis Screening Project that would offer a Mantoux Method Test to all persons visiting the screening center who are over 15 years of age. Approval was based on the fact that advice and consultation would be provided physicians as to handling of positive reactors; and that all positives will be referred to the family physician, if the patient has one, or to the local health department. Positives will be adequately and systematically followed up.
4. Declined to provide a refund of 1969 dues to a member because such was not Faculty policy, since benefits had been received and no financial need was demonstrated.
5. Received information as to the list of items on permanent loan to the Carroll County Farm Museum from the Faculty through the Carroll County Medical Society. Adequate protection, insurance, and recognition of the Faculty will be provided.
6. Agreed to seek a formal meeting with the Governor to discuss the health problems facing the citizens of Maryland.
7. Heard a brief report on the proposed revised JCAH standards and authorized a letter to be sent to JCAH urging the requirement for Pathology Departments be changed to read:

   > "The hospital shall assure the availability of pathological facilities, etc."

   rather than the proposed language which reads:

   > "The hospital shall maintain pathology facilities and services adequate to meet the needs of the patients."

   It also authorized publication of the report of the meeting in the JOURNAL to discuss these proposed standards. (The report will appear in the June issue.)
8. Selected an appointee to serve on the Advisory Committee on Foster Care of the State Department of Social Services.
9. Deferred taking action on proposed revised regulations regarding clinical laboratories.

Inner Sites...

In Cystitis...Azo Gantanol® focuses analgesic-antibacterial activity where it counts

The mucosa: specific analgesia usually within 30 minutes

Azo (phenazopyridine HCl) effects specific mucosal analgesia, relieving the dysuria, discomfort and burning which are virtually always a part of acute urinary tract infections.

Interstitial fluids: ready diffusion of antibacterial

Gantanol (sulfamethoxazole) is readily diffused into interstitial fluids to provide efficient antibacterial activity at foci of infection. This distribution, plus continuous antibacterial levels in blood and urine, has afforded effectiveness in the majority of infections in which it has been used.

Blood and urine: therapeutic antibacterial levels within 2 hours for up to 12 hours

Gantanol (sulfamethoxazole) produces prompt and prolonged therapeutic levels, in both blood and urine, with convenient *b.i.d.* dosage. Clinical response is usually obtained within 24 to 48 hours. The wide antibacterial spectrum of Gantanol includes *E. coli* and a variety of other susceptible gram-negative and gram-positive pathogens in urinary tract infections.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Urinary tract infections with associated pain or discomfort when due to susceptible organisms; prophylactically in urologic surgery, catheterization and instrumentation.

Contraindicated in sulfonamide-sensitive patients, pregnant females at term, premature infants, newborn infants during the first three months of life, glomerular nephritis, severe hepatitis, uremia and pyelonephritis of pregnancy with gastrointestinal disturbances.

Warnings: Use only after critical appraisal in patients with liver damage, renal damage, urinary obstruction or blood dyscrasias. If toxic or hypersensitivity reactions or blood dyscrasias occur, discontinue therapy. In intermittent or prolonged therapy, blood counts and liver and kidney function tests should be performed.

Precautions: Observe usual sulfonamide therapy precautions including maintenance of an adequate fluid intake. Use with caution in patients with histories of allergies and/or asthma. Patients with impaired renal function should be followed closely since renal impairment may cause excessive drug accumulation. Occasional failures may occur due to resistant microorganisms. Not effective in virus and rickettsial infections.

Adverse Reactions: Headache, nausea, vomiting, urticaria, diarrhea, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, skin rash, Stevens-Johnson syndrome, injection of the conjunctiva and sclera, petechiae, purpura, hematuria or crystalluria may occur, in which case the dosage should be decreased or the drug withdrawn.

Nutley, New Jersey 07110

Azo Gantanol®

(Each tablet contains 0.5 Gm sulfamethoxazole and 100 mg phenazopyridine HCl.)

Preludin® phenmetrazine hydrochloride

Indications: Preludin is indicated only as an anorexigenic agent in the treatment of obesity. It may be used in simple obesity and in obesity complicated by diabetes, moderate hypertension (see Precautions), or pregnancy (see Warning).

Contraindications: Severe coronary artery disease, hyperthyroidism, severe hypertension, nervous instability, and agitated prepsychotic states. Do not use with other CNS stimulants, including MAO inhibitors.

Warning: Do not use during the first trimester of pregnancy unless potential benefits outweigh possible risks. There have been clinical reports of congenital malformation, but causal relationship has not been proved. Animal teratogenic studies have been inconclusive.

Precautions: Use with caution in moderate hypertension and cardiac decompensation. Cases involving abuse of or dependence on phenmetrazine hydrochloride have been reported. In general, these cases were characterized by excessive consumption of the drug for its central stimulant effect, and have resulted in a psychotic illness manifested by restlessness, mood or behavior changes, hallucinations or delusions. Do not exceed recommended dosage.

Adverse Reactions: Dryness or unpleasant taste in the mouth, urticaria, overstimulation, insomnia, urinary frequency or nocturia, dizziness, nausea, or headache.

Dosage: One 25 mg. tablet b.i.d. or t.i.d. Or one 75 mg. Endurets tablet a day, taken by midmorning.

Availability: Pink, square, scored tablets of 25 mg. for b.i.d. or t.i.d. administration, in bottles of 100 and 1000.

Pink, round Endurets® prolonged-action tablets of 75 mg. for once-a-day administration, in bottles of 100 and 1000. (B)R3-46-560-B

Under license from Boehringer Ingelheim G.m.b.H.

For complete details, please see full prescribing information.

Geigy Pharmaceuticals

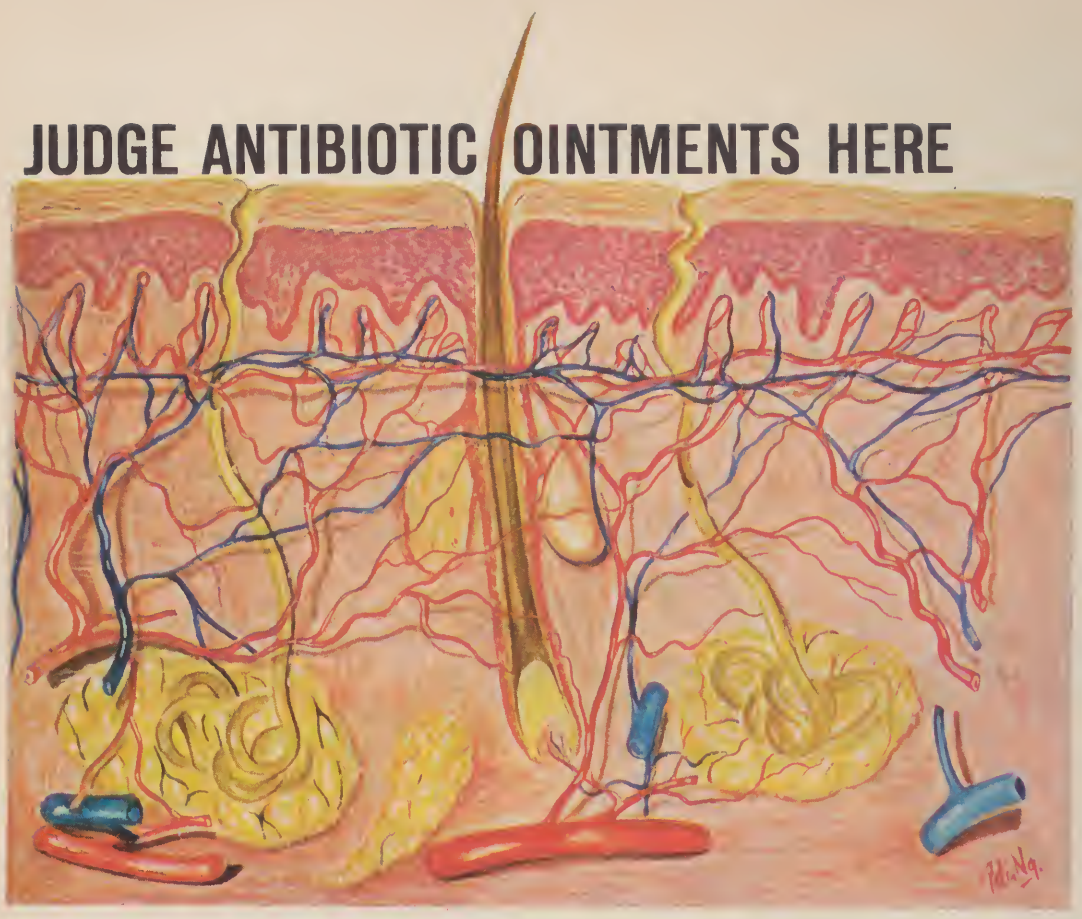
She runs a good chance of losing weight.

Exercise and Preludin run together in helping patients to lose weight.

Preludin often puts a curb on appetite and promotes a sense of well-being. By boosting a dieter's spirit, Preludin may help patients get the exercise you may prescribe.



The Endurets tablet taken between breakfast and midmorning usually provides daylong and early-evening suppression of appetite.

A few patients may experience overstimulation or insomnia. For a brief summary of all adverse reactions, precautions, warning and contraindications, please see the adjoining page.

Preludin® phenmetrazine hydrochloride

Endurets® prolonged-action tablets

JUDGE ANTIBIOTIC OINTMENTS HERE

Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Complete literature available on request from Professional Services Dept. PML.

Baltimore City
health department

Public Health and the Conquest of Disease in Baltimore, 1792-1968

The Baltimore City Health Department, whose concern is the health of almost a million urban dwellers, is the oldest existing health department in the United States. Its beginnings go back to 1792 when Governor Thomas Sim Lee appointed two physicians, John Worthington, MD, and John Ross, MD, as health officers, to prevent the spread of yellow fever from Philadelphia to Baltimore. That their efforts may have contributed to the prevention of an outbreak is recorded in a report of 1793, the year the Health Department was officially established, which stated that Baltimore was "free from Yellow Fever." From this beginning, Baltimore's public health agency has waged a constant war against the threat of sickness and premature death to Baltimore's citizens.[1-3]

JOSEPH GORDON
Director, Bureau of Health Information
Baltimore City Health Department

The Early Years

During 1797, the year that saw the incorporation of Baltimore as a city, two major health ordinances were enacted—Ordinance 11, dealing with the prevention of pestilential and other diseases, and Ordinance 15, concerned with preventive sanitary measures.[4] These ordinances have served as bases for all subsequent hygiene legislation in the city. From the beginning, the Medical and Chirurgical Faculty of Maryland, the state medical society, founded in 1799,[5] and the Medical School of the University of Maryland, established in 1807,[6] have been closely identified with the development of community hygiene in Baltimore and with the City Health Department. As early as 1802, only four years after the publication of Jenner's famous work on vaccination for the prevention of smallpox, the Medical and Chirurgical Faculty sponsored vaccination, and in so doing, was the first medical society in the United States to lend its support to this important foundation stone of preventive medicine.[7]

For the record, it is interesting to point out that Baltimore's public health agency preceded the establishment of others in Philadelphia, New York city, and Boston. The first British health officer was appointed in 1847, 54 years after the appointment of Baltimore's.[8]

Presented at The XIIth International Congress of The History of Science, Paris, France, August 26-31, 1968.

During the greater part of the past century, until its last decade, the major focus of health department service was concentrated mainly on the sanitation of the environment, the abatement of nuisances, and the collection of vital statistics. These were supplemented by such attention to the prevention of the communicable diseases, by vaccination and quarantine, as the science of the day permitted.

The last decade of the nineteenth century was a significant period for both the practice of medicine and the administration of public health. In Baltimore, it witnessed the rapid acceptance of the germ theory of disease by the medical profession and by the educated public. In 1893, The Johns Hopkins Medical School was opened.[9]

Uniquely, Baltimore's pestilential diseases were conquered before the turn of the present century. By 1900, the mosquito borne diseases—malaria and yellow fever—posed little threat. Their control was the result of the elimination of breeding places through the gradual improvement of drainage in the city, and elimination of standing water in streets, gutters, alleys and in cellars—activities constituting major health department efforts.

Cholera was present in Baltimore periodically from 1832 to 1879. Its conquest can be attributed similarly to an upgrading of environmental conditions, the water supply, and the control of insects and the disposal of human wastes.

The maritime quarantine of the port of Baltimore was part of the City Health Department services from the earliest time, even before the incorporation of the city. A small hospital was made available in 1794 for cases of smallpox and cholera. The diseases were brought into port by means of vessels from foreign lands. This port quarantine service was transferred to the United States Public Health Service in 1918. Since that time, it has been under the jurisdiction of this branch of the Federal Government.[10]

Recent Developments

The first two decades of this century witnessed three fundamental improvements that contributed greatly to Baltimore's health. These were the establishment of a pure water supply, an adequate sewage disposal system, and the enactment of a milk control ordinance.

During the same period there developed an increasing interest in the supervision of the health of school children and in the control of mortality from tuberculosis. Other important health services which have been established since 1915 are the Bureau of Child Welfare, organized in 1919, now known as Child Health Services, and the Bureau of Public Health Nursing, established in 1920, after a gradual growth beginning with the appointment of one school nurse in 1905.

The twenties marked the beginning of the end of the common communicable diseases. With the support and cooperation of the medical profession, campaigns were successfully conducted against diphtheria, tetanus, whooping cough, polio and, more recently, measles. Smallpox has not been a threat since 1928 when the last case was reported in the city.

Dental health is being achieved through fluoridation of water supplies begun in 1962, and the provision of services through clinics to needy school children.

Child lead paint poisoning, caused by nibbling painted surfaces, is another disabling illness that is slowly disappearing. The year 1965 was the first year without a single death from this cause since 1931 when records were started. From 1931 to 1967 a total of 1,111 children have been made ill from lead paint poisoning, and 136 of them have died.

Air pollution, radiation hazards, and other environmental hazards—all of which contribute to the dangers of our ever-growing metropolitan populations—are in the process of being controlled.

Tuberculosis, a leading cause of death in Baltimore in the early part of this century and in the 1800's, is slowly but surely being defeated through intensive case-finding and treatment efforts and computerization control methods.

The new killers, heart disease, cancer and accidents will move to lower levels when citizens learn how to cope with the pressures of modern day living, and become alert to cancer's danger signals.

Inherent in preventing premature death from heart disease and lung cancer is understanding the real danger in smoking cigarettes.

The prevention of accidents, particularly on the highway, remains unanswered. Perhaps the solution lies in the area of driver education, motor vehicle design, and more stringent laws to keep the irresponsible driver off the highway.

Infant and maternal deaths are being attacked through a special Maternity and Infant Services Project. And the health betterment of our inner city children is being achieved through a Com-

prehensive Children and Youth Project. Both of these programs are being conducted with federal assistance from the U.S. Children's Bureau. Many of these developments were accomplished under the administration of Huntington Williams, MD, Director and Commissioner of Health from 1931 to 1962, and his successor, Robert E. Farber, MD.[11]

Leading Causes of Death

Most Baltimoreans today die of causes different from their predecessors of over 100 years ago. In the annual report of 1849 the leading cause of death was tuberculosis with 668 deaths; next was infant deaths of unknown causes with 618 baby victims while an additional 411 infants were stillborn and 290 died of cholera infantum. Other leading causes included: old age, croup, dysentery, scarlet fever, and typhus fever.[12]

Leading causes of death today are somewhat different. A total of 4,537 residents died of heart disease in 1967; 1,938 succumbed to the various cancer causes and 830 persons died of stroke or related cerebro-vascular disease. Other leading causes today include accidents, diseases of infancy, influenza and pneumonia. While the causes of death have changed, the average life expectancy for a baby born today in Baltimore or elsewhere in the United States is 70 years compared with 47 years in 1900.[13]

Population and Area

The population of Baltimore in 1790 was 13,500; in ten years it doubled to 26,514; in 1850 it was 169,085; in 1900 it was 509,000; today, Baltimore's population of 910,000, almost double that of 1900, places Baltimore among the top ten populous cities in the United States. The city area is 91.9 square miles of which 13.2 square miles is water.

Current Organization and Financing

The Department today consists of 844 budgeted positions and 175 part-time employees. The services are organized into five major sections as follows: Administration, Local Health Services, Maternal and Child Health Services, Medical Care Services, and Sanitary Services.

Within the Administrative Section are found the Bureau of Health Information, which utilizes the mass media, radio and TV; Vital Records; Biostatistics; and Special Home Services. Under Local Health Services are included the five Health Districts; Public Health Nursing; Dental Care; Communicable Disease Control including the Venereal Diseases and Tuberculosis; Mental Health; and an Alcoholism Center.

The Sanitary Section consists of the Bureau of Milk Control, Food Control, Environmental Health, Meat Inspection, and Industrial Hygiene which includes both locally and federally funded Air Quality Control Programs. Laboratory services are provided by the Maryland State Department of Health.

The appropriation for the fiscal year 1967-1968 for work to be performed by the Health Department was $13,371,159, of which the city's share was $3,472,269 and the remainder provided from federal, state and other sources.[14]

Looking Ahead

In view of current and projected Health Department programs the outlook for improved health records is most favorable. Plans are now underway to provide a further expansion of city services through the Mayor's decentralization of governmental services to the neighborhood level. In this the Health Department which has been on a neighborhood basis, almost since its inception,[15] stands ready to provide additional services where needed.

The future also holds promise for greater strides against communicable and chronic diseases and mental illness. New drugs, new therapies and new programs should ameliorate the problems of emotional illness, alcoholism and drug addiction.

As for our aging population—a start has been made to improve their health through medical and aid programs made possible by federal, state and local funds.

In this, and in other aspects of living, the continuing joint efforts of our public and private agencies—federal, state, and local—will make for better health not only for the residents of Baltimore, but for America and the world, for in the conquest of disease there is mutual cooperation between all nations.

But there is one last point that should be made clear—none of this will happen unless each assumes a personal responsibility for improving his own health and environment, and that of his neighbors and his community.

Public Health is individual health.

JAMES E. CARSON, MD, COMMISSIONER
KURT GORWITZ, ScD, STATISTICS DIRECTOR

Maryland State department of mental hygiene

The National Scene

Expenditures in the United States in 1968 for the maintenance of state and county operated mental hospitals exceeded 1½ billion dollars.* This figure was larger than the total budget of Maryland, and all but a few of the most populous states. It reflected a record increase of 162 million dollars, or 11.5%, over the previous year's comparable figure. Total costs have nearly doubled since 1958, and are now almost 50% higher than they were five years ago.

Hospital expenditures have continued to go up, although the average number of patients in these facilities has decreased steadily. Nationally, a 24.4% decline in the patient population (from 546,337 to 412,818) occurred between 1958 and 1968. As a result, the average daily cost of caring for one patient rose from $4.04 to $10.47 during this ten-year period. Maryland, with a reported figure of $11.30, continued to rank approximately midway, between the high of $36.06 for Alaska and the low of $4.81 for Mississippi. Despite patent improvements, these figures indicate a widespread continuing lag behind comparable cost data for general hospitals, as well as for federal (V.A.) psychiatric hospitals.

FISCAL YEAR	*AVERAGE SIZE OF PATIENT POPULATION*	*NET LIVE RELEASES*	*TOTAL EXPENDITURES*	*EXPENDITURE PER NET RELEASE*
1958	546,337	161,884	$ 805,861,786	$4,978.02
1960	539,184	192,818	916,236,166	4,751.82
1962	519,742	230,158	1,033,567,884	4,490.68
1964	496,661	268,616	1,144,024,206	4,258.96
1966	460,910	308,636	1,300,380,295	4,213.31
1968	412,818	351,461	1,577,631,758	4,488.78
PERCENT CHANGE (1968 vs. 1958)	−24.4	+117.1	+95.8	−9.8

If present trends continue, the average daily cost per patient must be expected to rise 10% or more per year, even though the average total cost of each episode declines further. The only alternative to continuing, uninterrupted increases in state psychiatric hospital expenditures is to reduce drastically the size of patient populations by 1) providing community centered programs as an alternative to hospitalization, 2) further decreasing the average length of hospitalization, 3) transferring chronic, custodial patients to nursing home type facilities, and 4) developing and expanding aftercare services for released patients. These can be accomplished through closely coordinated and centrally directed programs offering a variety of community and hospital services to the mentally disturbed, and through the implementation of current and new concepts for the prevention of mental illnesses.

While these data reflect rising personnel-patient ratios, the current emphasis on psychopharmacology, and other innovations in treatment services, they are primarily related to the rapidly increasing patient turnover, resulting from shortened periods of hospitalization for new admissions and the transfer of many long term patients to nursing homes. As indicated in the above table, releases more than doubled between 1958 and 1968. In fact, this rise has been so large that the average expenditure required to produce one net release is now 9.8% less than it was ten years ago.

* Office of Biometrics, National Institute of Mental Health, Provisional Patient Movement And Administrative Data, State And County Mental Hospitals, United States, July 1, 1967-June 30, 1968.

WILLIAM J. PEEPLES, MD, MPH, COMMISSIONER

Maryland State department of health

Measles Morbidity In Maryland

Below is a chart reflecting Measles Morbidity in Maryland during the period 1961 through 1968. The dramatic drop in measles cases is directly related to the widespread administration of measles vaccine which was begun in the latter part of 1966.

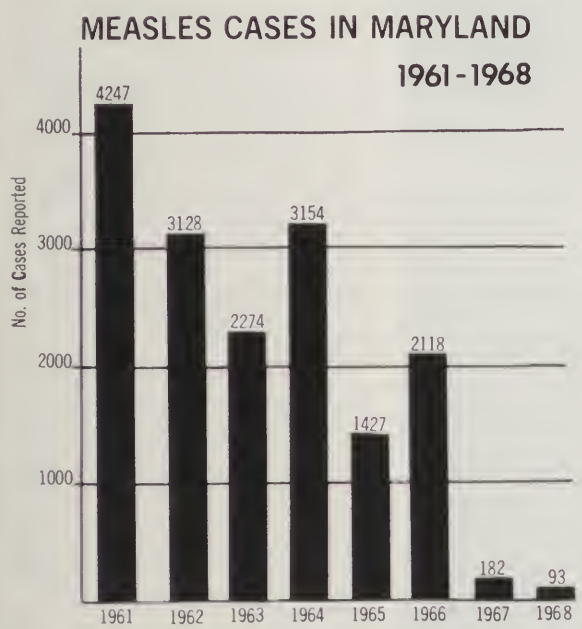

Chart prepared by the Division of Communicable Disease shows dramatic drop in measles cases.

Through mass measles vaccination campaigns on "Measles Sundays," in elementary school "mop-ups," and in health department clinics, over 215,000 children have been immunized since July 1, 1966. These efforts, along with the vaccinations given in private physicians' offices, have accomplished the near eradication of measles in Maryland.

Through the first eight weeks of 1969, five cases of measles have been reported and confirmed. This compares with 28 cases for the same period last year, and an expected 286 cases on the basis of the five-year median.

Although complete eradication may not be attainable, a continuing effort will have to be made to vaccinate all children and, thus, maintain a high level of immunity. So far, a good job has been done, but physicians cannot afford to slacken their efforts or they may have to do the job all over again. They should also be sure that all reported cases are true measles.

A flyer urging continuous efforts to control measles is being sent to physicians throughout the State in the very near future.

a broad-spectrum antibiotic for the diabetic:

threat or therapy?

Disordered metabolism makes her prone to bacterial infection —and to moniliasis.

When she needs tetracycline, she may also need protection against the threat of fungal overgrowth. And Tetrex-F can provide both.

Each capsule contains 250 mg. of tetracycline phosphate complex to control sensitive bacterial pathogens... and nystatin, 250,000 units, as a precautionary measure against troublesome vaginitis, proctitis or other monilial infections. However, superinfection with other, nonsusceptible organisms may occur.

Tetrex-F®
(tetracycline phosphate complex-nystatin)

PRESCRIBING INFORMATION: Tet-F. 5—2/23/67. For complete information consult Official Package Circular.
Indications: Infections of respiratory, gastrointestinal and genitourinary tracts and skin and soft tissues due to tetracycline-sensitive organisms, in patients with increased susceptibility to monilial infections.
Contraindications: The drug is contraindicated in patients hypersensitive to its components.
Warnings: Photodynamic reactions have been produced by tetracyclines. Natural and artificial sunlight should be avoided during therapy. Stop treatment if skin discomfort occurs. With renal impairment, systemic accumulation and hepatotoxicity may occur. In this situation, lower doses should be used. Tooth staining and enamel hypoplasia may be induced during tooth development (last trimester of pregnancy, neonatal period and childhood).
Precautions: Bacterial superinfections may occur. Infants may develop increased intracranial pressure with bulging fontanels. In gonorrheal therapy, serologic tests for syphilis should be conducted initially and monthly for 3 months.
Adverse Reactions: Glossitis, stomatitis, nausea, diarrhea, flatulence, proctitis, vaginitis, dermatitis, and allergic reactions may occur.
Usual Adult Dosage: 1 capsule q.i.d. Continue for 10 days in Beta-hemolytic streptococcal infections. Administer one hour before or two hours after meals.
Supplied: Capsules, bottles of 16 and 100. Each capsule contains tetracycline phosphate complex equivalent to 250 mg. tetracycline HCl activity and 250,000 units of nystatin.
For Oral Suspension, 125 mg. tetracycline and 125,000 u. nystatin/5 ml., 60 ml. bottles. **A.H.F.S. Category 8:12**

Drugs and Driving

Gerard D. Dobrzycki, MD
Resident in Preventive Medicine
Maryland State Department of Health

From the Subcommittee on Traffic Safety of the Medical and Chirurgical Faculty of the State of Maryland

What are the basic requirements of a driver today? Dr. Ross A McFarland, Professor of Environmental Health and Safety at Harvard School of Public Health, lists the basics as, alertness and attention, judgment, coordination, perception of movement and distance, and ability to read signs.[1]

Before you take the wheel...

consult your doctor about

the side effects of any drugs you take.

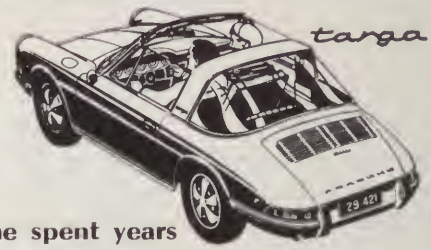
Drugs either self-administered or prescribed by the physician can produce effects which can alter these basic requirements. The degree of effect covers the entire spectrum of impairment, depending on the severity of the drug reaction. Physicians must be alert to the fact that drugs, which are usually considered as having no side effects, can cause reactions in a few individuals which could markedly effect their driving ability. Keeping this thought in mind, it is obvious that the physician should not only concern himself with the effect of the prescribed medication on the patient's disease process, but also of its effect on the patient's normal daily activities.

The following is a resumé of a few of the more important groups of drugs that can cause untoward reactions which effect ones driving ability:

- Anti-Motion Sickness and Antihistamines:
  These frequently cause dizziness, drowsiness, and nervousness. Other less frequent effects are blurred vision, vertigo, restlessness, and a number of manifestations of their sedative action.
- Central Nervous System Depressants:
  Drugs such as morphine and meperidine, frequently cause dizziness, drowsiness, euphoria, and a decreased ability to concentrate.
- Central Nervous System Stimulants: Drugs such as the amphetamines mask fatigue, and may effect judgment. In large doses, one can experience headache, dizziness, agitation, irritability, and inability to concentrate.
- Hypnotics and Sedatives: These drugs not only cause drowsiness and sleep, but will synergize with ingested alcohol, and thus compound the side reaction.
- Tranquilizers: These can effect mental alertness, cause drowsiness, ataxia, and confusion. Paradoxical reactions such as excitement, stimulation, and acute rage, have been reported in some patients.
- Sulfonamides: Patients on this type of medication may experience headaches, nausea, dizziness, weakness, and poor coordination.

Since it is impossible to predict who will experience any untoward reaction, a few guidelines

for the physician when he is prescribing medication for his patient are listed:



1. Could the medication being described affect the patient's physical ability?
2. Could the medication affect his mental ability?
3. Could the drug affect the patient's vision and hearing?
4. Could the drug affect the patient's judgment?
5. Could the medication affect his emotional makeup?

If the answer to any of the above questions is yes, then the patient should be adequately warned as to hazard involved in driving a vehicle.

rehabilitation notes

Various Pain Syndromes Which May Result from Osteoarthritis of the Cervical Spine

LEE H. RILEY, JR., MD
Associate Professor of Orthopaedic Surgery
Johns Hopkins University
School of Medicine

Arthritis Foundation Series
The Arthritis Foundation
(Maryland Chapter, 12 West 25th St., Balto., Md. 21218) is arranging a series of articles by experts on arthritis to appear from time to time in Rehabilitation Notes.

Osteoarthritis of the cervical spine may produce pain in several ways. Among the mechanisms which may be involved are:

1) Direct compression of neural tissue, either nerve roots or the spinal cord, associated with muscle weakness and objective sensory abnormalities following a dermatome distribution.[1-4]

2) Compression or irritation of the vertebral artery and the accompanying posterior cervical sympathetic plexus in their position on the posterior lateral aspect of the vertebral body by osteophytes originating either from the uncovertebral articulations (joints of Luschka), or from the facet joints. Symptoms resulting from transient insufficiency of the vertebral artery or from irritation of the accompanying sympathetic plexus can be vague, and are difficult to document, but may include headaches, tinnitis and vertigo, as described initially by Barre[5] in 1926, and more recently by Jung and Vierling[6] in the French literature, and by Sheehan, Bauer, and Meyer,[7] Chrisman and Gervais,[8] and Stewart[9] in the American literature.

3) Thoracic outlet compression of a major or minor degree resulting from increased tone in the scalene muscles, secondary to a primary abnormality within the cervical spine, with or without neural tissue compression. Many cases, designated as the so-called scalenus anticus syndrome, which are not associated with a cervical rib or a high thoracic scoliosis, may result from early degenerative cervical disc disease in an individual in whom the thoracic outlet was just adequate under ideal circumstances, but not adequate following the onset of degenerative change in the cervical spine with a resulting increase in tone of the scalene muscles. The neuro-physiological mechanisms which make such a concept permissible have been described by McCouch, Deering and Ling.[13] Pain resulting from brachial plexus compression is usually centered in the supraclavicular region and radiates into the arm and hand. It is generally increased by use of the arm, and relieved by rest. Occasionally, blanching of the hand is noted in association with pain if vascular compression is present. Tenderness is usually present over the brachial plexus, diminution or occlusion of the

radial pulse can be produced by the Adson maneuver, and neurological examination suggests compression of the brachial plexus.

4) Stimulation of the fine unmyelinated nerve fibrils with simple nerve endings which are found in the annulus fibrosis of the intervertebral discs, and also in joint capsules elsewhere resulting in stimuli which, on reaching the higher centers of the brain, are interpreted as representing pain or parathesias in the neck, in the lateral aspect of the arm, in the hand, in the tip of the shoulder, along the medial aspect of the scapula, or within the upper thoracic spine.[10-12] Evidence of direct compression of neural tissue such as, muscle weakness, reflex changes, and objective sensory changes are not noted unless, of course, neural tissue compression is also present.

In a given patient, one may see pain secondary to all four mechanisms. Separating them is at times impossible, in that symptoms of each overlap the other three, but an attempt to do so should be made whenever possible so that the primary lesion, whether it be an osteophyte producing neural tissue compression, a degenerative change involving an intervertebral disc, or a compromised thoracic outlet, may be diagnosed and properly treated.

By far the largest group of patients seen for evaluation of neck and upper extremity pain, resulting from osteoarthritis of the cervical spine, do not have evidence of significant brachial plexus compression, nor of vertebral artery irritation, nor of actual nerve root or spinal cord compression. The pain of which they complain is not radicular in nature, but rather dull, diffuse pain which may be felt in the base of the neck, along the vertebral aspect of the scapula, about the tip of the shoulder, the lateral aspect of the arms, or into the hands. Such pain may also be referred to the sub-occipital area of the skull and, on occasion, to the retro-orbital areas. These patients do not complain of hypothesia, but rather of painful parathesias in the arms and hands, which many describe as a "sandy" feeling. The mechanism of pain in this group of patients is irritation of the fine unmyelinated nerve fibrils which innervate the capsules of arthritic facet joints and the annulus fibrosis of arthritic intervertebral discs by motion of the involved intervertebral levels, as previously described.

Limitation of neck motion, production or intensification of pain by prolonged extension of the neck, pain on vertical compression of the cervical spine, and tenderness to palpation over the spinous processes of the cervical vertebra posteriorly, and over the intervertebral disc spaces anteriorly, are often noted on physical examination of these patients. None of these physical findings are truly objective determinations, but depend upon the patient's interpretation of maneuvers performed by the examining physician. If, however, the patient is not preconditioned as to the expected response, these tests have a high degree of reliability and when present, strongly suggest that symptomatic osteoarthritic changes are present within the cervical spine.

If the history and the physical examination strongly suggest such a diagnosis, and if disc space narrowing and bone spur formation are present at one or more levels within the cervical spine, the diagnosis may be made with a fair degree of certainty. On the other hand, if plain X-rays of the cervical spine do not reveal the bony changes suggestive of osteoarthritis. More sophisticated radiographic techniques may be indicated, such as, myelography, discography, and cinefluoroscopy.

Myelographic changes, frequently seen in the early stages of osteoarthritis of the cervical spine before disc space narrowing and spur formation are apparent, include posterior displacement of the dural sheath at the involved intervertebral level in the lateral view, and, in the AP view, central thinning of the dye column. These changes are the result of early fibro-chondro-osseous proliferation at the involved intervertebral disc space, and may precede the development of bone spurs by several years. It must be emphasized, however, that such findings would have no significance if the history and the physical examination did not strongly indicate the diagnosis.

Positive discography findings likewise will have no significance in an individual whose history and physical examination do not strongly suggest the diagnosis.

Cinefluoroscopy of the cervical spine will reveal limitation of motion, asynchrony of motion, or even subluxation at the abnormal intevertebral level. Again, as in the case of myelography and discography, such findings are of no significance unless the history and the physical examination strongly suggest the diagnosis of symptomatic cervical osteoarthritis.

In the absence of nerve root or spinal cord compression, surgery should not be considered initially in the treatment of osteoarthritis of the cervical spine. In most instances, mild analgesics

such as acetylsalicylic acid, and cervical traction used by the patient at home, when necessary, will be sufficient. But, it is important to remember that cervical traction must be properly applied. If it is not, and if the neck is maintained in an uncomfortable position (particularly in extension), symptoms will be increased rather than decreased by this technique. Pain of brachial plexus compression in the thoracic outlet is usually intensified rather than relieved by cervical traction; this point should be considered in the differential diagnosis. Less than ten pounds of cervical traction, applied with the neck in the most comfortable position, usually will temporarily relieve discomfort due to cervical osteoarthritis; it may be applied with the patient sitting or lying. The time spent in traction each day should correspond to the degree of discomfort experienced by the patient, and is best determined by him. That is, when neck pain subsides, traction is no longer necessary and the patient may relegate the home cervical traction unit to the closet until the next episode of pain, which may be days, weeks, or months later. Generally, at least 30 minutes of cervical traction two or three times a day is necessary, but much longer periods in traction may be necessary when acute pain and muscle spasm are present. A mild sedative and a muscle relaxant are useful in the treatment of acute attacks.

Anterior cervical fusion of the involved intervertebral levels is associated with a high degree of excellent results in those few patients who do not respond to conservative treatment. Surgical treatment should not be denied the rare individual who has not responded to conservative treatment, for prolonged pain is associated with a definite emotional response which may be more disabling than the pain itself. In a recent review of a group of my personal patients, surgically treated for unrelenting neck pain which had been present for an average of 31 months, the emotional response to long standing pain was what eventually disabled the patient, rather than the immediate disabling effects of the pain itself. As a group, they were depressed and irritable. Anxiety, despair, inability to concentrate, and agitation were prominent characteristics. Naturally, none of these are prone to generate a warm physician-patient relationship, unless the physician appreciates that they are the normal responses to long standing pain. The encouraging feature is that these characteristics disappeared following successful relief of pain. The patients returned to productive roles in society, the psychological improvement continued, and the patients were not disposed to seek surgery for other conditions.

RESIDUAL PULMONARY FINDINGS IN CLINICAL HYALINE-MEMBRANE DISEASE

Follow-up of 70 infants who had had hyaline-membrane disease at birth revealed that six had X-ray evidence of pulmonary fibrosis or overexpansion or both. These sequelae appear to result from the reparative process to the original insult to lung tissue.

Pulmonary sequelae are known to occur in infants who survive hyaline-membrane disease, but the frequency and origin of such sequelae are not known. The study reported was undertaken to examine the relation between certain aspects of the acute episode and the clinical forms, and long-term course of children surviving hyaline-membrane disease in infancy.

Between September 1961, and June 1965, 90 infants were discharged from the premature nursery of Vanderbilt University Hospital as having recovered from clinical hyaline-membrane disease. Adequate follow-up examinations and X-ray studies were available for two or more years on 70 of the children. The ratio of boys to girls was 2:1, which is typical of experience with hyaline-membrane disease.

Among the 70 children were 19 infants who had required prolonged ventilatory assistance in a respirator. The 51 infants who had not required such care were less severely ill than those who did.

During the follow-up period, 17 in the non-respirator group had pneumonia, bronchiolitis, or both. Two of the infants who had had respirator care had an unusual sequence of respiratory illnesses. Although mildly abnormal X-ray findings at follow-up did not appear to be related to clinical or biochemical values recorded during the period after birth, at least one X-ray film of each of six children had "moderate" over-all abnormalities. All had mild pulmonary fibrosis, and five had moderately extensive infiltrates at some time.

Hypoxia Severe

These six children had been severely ill and had required respiratory therapy for 34 to 116 hours. They had a tendency to more severe hypoxia than the other respirator-treated children, but the difference was not significant.

The two infants in the respirator group with the unusual sequence of illnesses had frequent severe episodes of pulmonary overexpansion associated with expiratory wheezing, rales, and rhonchi, for which they were hospitalized frequently during the first two years of life. There was no history of allergic disorders in the families of these children, and the wheezing and overexpansion did not respond to epinephrine as would have been expected of allergic bronchospasm. The findings of diffuse, patchy peribronchial and alveolar fibrosis suggest that this may represent an uncommon sequel to clinical hyaline-membrane disease.

In all six children the radiological abnormalities observed were increased parenchymal markings suggestive of pulmonary fibrosis, overex-

Frank M. Shepard, MD; Richard B. Johnston, Jr., MD; Eugene C. Klatte, MD; Henry Burko, MD; and Mildred Stahlman, MD. *The New England Journal of Medicine*, November 14, 1968.

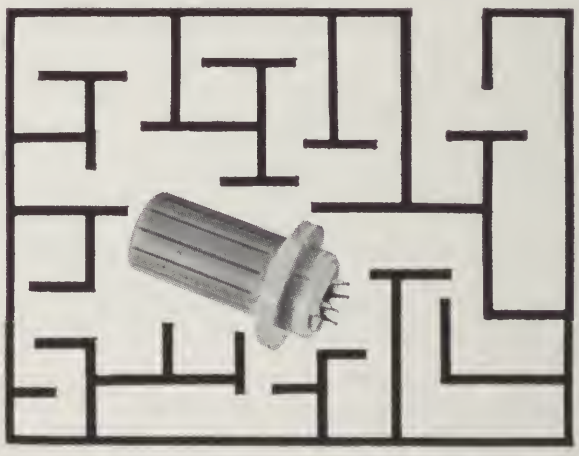
panded lung fields, and infiltrates. These infants were among the 19 who had such severe hyaline-membrane disease that the use of prolonged negative-pressure ventilatory assistance was required for survival. The question is whether this residual pulmonary disease is an inevitable part of the recovery process from severe hyaline-membrane disease, or whether this is an iatrogenic disorder secondary to oxygen administration, respirator therapy, infection, poor pulmonary hygiene, or other possible factors.

Immaturity Not Responsible

Immaturity did not appear to be the sole cause of the radiological and clinical abnormalities noted at follow-up. There was no evidence of intrauterine bacterial pneumonia or extensive secondary bacterial pneumonia to suggest that superimposed infection at the time of the acute difficulty was a factor in the production of residual disease in these children.

In the management of severe clinical hyaline-membrane disease, it is common for the infants to be exposed for prolonged periods to high concentrations of oxygen to combat severe hypoxia. Oxygen toxicity has been suggested as the probable explanation for the severe process in infants so treated.

However, a careful study of infants dying with hyaline-membrane disease suggests a prenatal event that initiated pulmonary arteriolar constriction, leading to loss of nutritional blood supply to the lung. This is followed by necrosis, slough, and hyalinization of the bronchiolar and alveolar duct epithelium associated with an exudation of protein-containing fluid into damaged areas. A loss of pulmonary surfactant has been shown to be associated with these events, together with reduced compliance and the development of atelectasis. Vascular damage or a coagulapathy related to the initiating insult may account for the pulmonary hemorrhage occasionally seen.



Reparative Process

In infants who survive extensive tissue injury, the subsequent reparative process could result in the peribronchial and alveolar fibrosis, such as was seen in the cases in this series and has been reported by others. Such lesions might possibly predispose the infant to respiratory infection and result in a fixed or progressive course of pulmonary fibrosis and overexpansion, with clinical and radiologic manifestations of chronic pulmonary disease.

On the basis of evidence so far reported, oxygen toxicity alone cannot be held responsible for the changes observed. Indeed, the prolonged exposure of the infants in this series to high oxygen concentrations was dictated by clinical and biochemical evidence of a degree of anoxemia that demanded correction for survival.

None of the infants in this series treated with negative-pressure respirators and high oxygen concentrations had late progression of pulmonary symptoms leading to death. In only two cases was positive-pressure ventilation also necessary for more than one hour. Arterial oxygen tension, carbon dioxide tension, and pH were repeatedly monitored throughout the course of the disease when more than 40% oxygen was used. Prolonged hypercapnia was never a serious problem in the post-respirator period.

There was no evidence that pulmonary infection due to gram-negative organisms, which often complicates prolonged endotracheal intubation, occurred, nor was there evidence of environmental inhalants such as silica dust as a cause of the persistent pulmonary disease.

HISTO IS CONFUSING.

Histoplasmosis can mimic such unrelated diseases as TB, leukemia, pneumonia and syphilis. Use the blue Histoplasmin LEDERTINE™ Applicator as the first step in differential diagnosis and as a routine step in physical examinations for the permanent records of your patients.

HISTOPLASMIN, TINE TEST

(Rosenthal)

Precautions—Nonspecific reactions are rare, but may occur. Vesiculation, ulceration or necrosis may occur at test site in highly sensitive persons. The test should be used with caution in patients known to be allergic to acacia, or to thimerosal (or other mercurial compounds).

Chronic Cor Pulmonale

Cor pulmonale may be defined as failure of the right ventricle, caused by abnormal physiologic function within the lung parenchyma or pulmonary vasculature. It is most commonly observed in patients with chronic bronchitis and emphysema; it is towards this group that the discussion will be directed.

DAVID G. SIMPSON, MD
Associate Professor and Head
Division for Pulmonary Diseases
University of Maryland School of Medicine

These diseases most often occur in combination, but the importance of bronchial obstruction in considering the etiology of cor pulmonale is demonstrated by the observation of right ventricular failure in patients who have chronic bronchitis without emphysema. Differentiation of the effects of bronchitis from those of emphysema is not difficult but demands a more sophisticated attitude than that which permits ready acceptance of the broad classification of "Chronic Obstructive Pulmonary Disease."[1]

Chronic bronchitis is defined as a chronic productive cough in patients who do not have another specific identifiable pulmonary or cardiac cause. In this disease, ventilation is decreased in the areas of the lungs obstructed by secretions. The perfusion of blood in these areas may be normal or almost normal so that the underventilation is out of proportion to the blood flow. This results in a decreased, arterial-blood-oxygen tension and, with more severe disease, an increased, arterial blood, carbon dioxide tension, producing respiratory acidosis in addition to the hypoxemia. The result is pulmonary arterial hypertension and, ultimately, right ventricular failure.

Patients in cor pulmonale most often have a combination of chronic bronchitis and emphysema. The diagnosis of chronic bronchitis, as noted, may be made from the history, but only in the moderate or severe forms can this be confirmed by physical examination: by the presence of wheezes, a prolonged expiration, rhonchi, or persistent rales over the lower one third of the lungs. The breathing sounds may be of poor quality if bronchial secretions have caused severe obstruction.

The definition of emphysema is based on pathological description: a state of overdistension of the lungs associated with loss of elasticity, with an essential feature, disruption of alveolar walls or "departitioning." With minimal involvement, em-

physema cannot be detected clinically. But when of significant severity, clinical and roentgenographic findings are reliable. An increased anteroposterior diameter of the thorax is more commonly the result of kyphosis than emphysema, and is more often observed in the short, squat, overweight patient with bronchitis, than in the elderly, underweight patient with emphysema. The manubrio sternal angle may, however, be abnormally prominent because of the overdistension and increased use of the accessory muscles of respiration. Additional evidence of overdistension of the lungs and fixation of the thoracic cage is seen in the decreased thoracic expansion, the decreased diaphragmatic excursion, and the increased resonance with some loss of cardiac and liver dullness. The breath sounds are diminished, and there is little increase with voluntary hyperventilation. Over the upper lobes, the breath sounds are louder than over the lower lobes—the result of the altered thoracic movements.

Examination of the chest roentgenogram allows confirmation of overdistension and disruption of lung parenchyma: the low flat diaphragm, best appreciated in the lateral and oblique views, the enlarged area of retrosternal translucency as observed in the lateral film, and attenuation of the peripheral vasculature. In the patient whose dysfunction results mainly from emphysema, the cardiac shadow is small and this is exaggerated by the low position of the diaphragm. But with a combination of diseases, severe enough to cause pulmonary arterial hypertension, there is first enlargement of the pulmonary outflow tract and later, enlargement of the transverse diameter of the heart, the right ventricular contribution to this being best appreciated in the right anterior oblique film.

Severe emphysema does not occur without some bronchitis, however insignificant. There is, therefore, no patient within this group to whom some help cannot be offered. The basic principle of treatment of cor pulmonale is the relief of hypoxemia. This may be effected by one of two methods: the provision of an increased alveolar oxygen tension, or improvement of the volume and distribution of ventilation.

A disposable mask, which applies the Venturi principle, permits the delivery of a 24% or 28% oxygen mixture from an oxygen tank, and provides a significant increase in alveolar and arterial-blood-oxygen tension without removing the hypoxic stimulus to respiration. Serial determinations of arterial-blood-gas tensions are essential.

The second method involves the use of a positive-pressure device. This may be successfully applied intermittently, if the condition of the patient allows and if medical, technical, and nursing personnel are available for constant care. If this is not feasible, ventilation must be assisted or controlled. With either method, the patient must be efficiently connected to a respirator. An endotracheal tube is preferable and may safely remain in place for 48 to 72 hours, after which a tracheostomy may be substituted if continuous ventilatory assistance or control is required. During assisted ventilation, the patient controls the pattern of breathing; during controlled ventilation, it is dictated by the ventilator, and appropriately adjusted to the needs of the patient. Adequate humidification of the inspired gas must be maintained, but the only additional aerosol which is useful is a topical bronchodilator, saline or water. The so-called detergents are of no value, and the only actions of the available mucolytic agents are to produce an unpleasant taste in the mouth and to interfere with the mechanical efficiency of the respirator.

Simultaneous correction of dehydration is important, even in the presence of the peripheral signs of congestive cardiac failure. The removal of secretions by efficient, safe, suctioning methods is then possible. The patient in respiratory failure is best treated in a Respiratory Care Unit.[2]

Other forms of treatment of cor pulmonale are less important. Digitalis is usually prescribed, but the need for this is considerably less than in the treatment of left ventricular failure. The importance of diuretic agents, too, has been overemphasized; the relief of hypoxemia usually results in a spontaneous diuresis, and diuretic agents too often cause abnormalities of electrolyte balance, particularly potassium. In the polycythemic patient, the need for phlebotomy is also secondary to the above measures. The hematocrit may be returned to normal or near normal levels by repeated removal of a small volume of blood (350 cc) over a period of several days. An antimicrobial agent, such as one of the tetracyclines or one of the synthetic penicillins, is often prescribed. But in the absence of roentgenographic evidence of pneumonia which, when present, is usually accompanied by pyrexia and a leucocytosis, the agent probably has little effect. Pneumonia is relatively uncommon, and the mechanical removal of secretions is

more important than attempts to eliminate "infection."

Obviously, these patients should not smoke. The stand-by of maintenance therapy is the effective application of a bronchodilator. Patients must be taught the following procedure: to exhale slowly to avoid air trapping, to synchronize the release of the aerosol with the beginning of inspiration, and to inhale deeply, and hold the breath for an instant, two or three times. This should be repeated three or four times daily.

The effects of chronic bronchitis and emphysema are established before patients become incapacitated. For most patients, the progression is a steady process of deterioration which may be predicted, but for some patients prediction of the future course is impossible.

For Safe, Sure, Speedy Relief —
— Get RESINOL GREASELESS!

Medical Scientists have conquered 6 dread diseases in the past decade, but they are largely in the dark, they admit, in finding relief for one age-old ailment—itching

New remedies containing antibiotics have been tested, but have often caused side effects which are worse than itching skin. After many years of research and testing, Resinol Greaseless Cream was developed. . . . A doctor's formula containing safe yet powerful ingredients, Resinol Greaseless contains an amazing, proven "anti-itch" medication called Resorcin, which quickly and effectively relieves most any kind of itching. Try Resinol Greaseless . . . You'll be delighted to find that it really works! At all drug stores. Buy a tube today.

Federal Action Against Pooled Plasma

Another extraordinary chapter in the advance of federal regulation of the practice of medicine was written in March 1968 when the Committee on Plasma and Plasma Substitutes of the National Research Council, on patently insufficient grounds, categorically condemned the use of pooled plasma in medicine. The Division of Biologics Standards of the National Institutes of Health quickly enforced the pronouncement in May 1968 with the withdrawal of all plasma licenses.

The remarkable series of events occurred after a successful background of over 16 years of safe and efficacious use of plasma by a multitude of blood banks and clinicians. Numerous users, reporting their experiences with pooled plasma subjected to controlled temperature storage, have found that not only did its efficacy exceed that of whole blood transfusion in selected conditions of chronic plasma loss, but also that the safety factor exceeded that of whole blood transfusion.

In April 1968 a paper by Redeker, reporting the experience of commercially prepared pooled plasma use, appeared simultaneously with a statement of condemnation of pooled plasma by the National Research Council. This paper described a prospective study involving 120 patients who had bilirubin and enzyme determinations following plasma infusion and liver biopsy when elevations developed in these laboratory measurements. The control group was a series of 45 patients treated during the same period with albumin alone. The incidence of clinical and laboratory hepatitis was 10% in the plasma-treated group and 0% in the control group.

The gaps in this paper, used as prima facie evidence to outlaw pooled plasma for the nation, are as obvious as the preconceptions in the accompanying NRC statement. The paper admits that 50% of the cases were anicteric, proved by laboratory tests only. Deleting the anicteric cases still leaves an incidence of clinical hepatitis of 5%, which is in marked variance with all previously published work. The latter, cumulatively representing many thousands of cases, reported an experience of post-plasma hepatitis between 0% and 2%. Morbidity and mortality statistics were not presented. Liver biopsies were not described. There was no attempt to report the degree of severity of the hepatitis; it can be inferred from the description of the anicteric cases that most were quite mild.

The paper describes huge pools averaging 178 donors each, from commercial sources. This is in contradistinction to the work of others who used pools of 17 to 41 donors with a subsequent marked variance in the incidence of transmitted hepatitis. The concept presented in this paper, that the size of the pool bears no relationship to the incidence of hepatitis, is open to serious question. Further, there was no mention of any attempt (beyond NIH licensure) to inspect or control the plasma source. All are aware of the problems surrounding blood products from commercial sources.

The NRC Committee statement says that to refute findings cited in this study would require

additional data needing sizeable resources, effort, and time; and assumes that, therefore, the possibility that this work will be repeated is slight. They then acted rapidly to insure the sanctity of this work by outlawing the use of plasma, thus, effectively minimizing even more the possibility that the work would be repeated. Nevertheless, further work is needed since many unanswered questions remain. For example, it may be that the milder, anicteric cases of hepatitis are not infectious hepatitis at all, but rather antigen-antibody reactions resulting from a large amount of killed virus contained in large pools from paid donor sources. The only way to test this theory would be to attempt to transmit icteric hepatitis from anicteric recipients. The NRC ruling deletes consideration of such study *except* on an illegal or clandestine basis, the results of which could not be made public readily.

The study upon which the ruling was based was highly touted by the NRC Committee as a prospective, controlled one. Prospective it was, in that recipients of plasma were followed carefully after infusion. Controlled, it was not. No control of the source of plasma or the pool size was described or apparently exerted. This limited and unconfirmed study has equated all plasma with that used in this study. As a result, it has outlawed all of it, while completely ignoring far more extensive previous experience and the accumulated opposing evidence. When this study finds a 5% incidence of icteric hepatitis as opposed to the 0% to 2% incidence in extensive prior reports, something must be amiss.

Cogent arguments against the use of pooled plasma are available. Just as with the transfusion of whole blood, there is a small but distinct risk of transmitting hepatitis so that when albumin will serve equally well, it is used. However, equally strong arguments for the use of pooled plasma in selected conditions are available. To condemn the use of pooled plasma is to work to the detriment of the idea of component blood therapy—an integral part of modern medicine. There is significant economy to be gained from plasma, which is a natural by-product of blood bank operations. Although economy is not the total argument or even the major one, it is significant, especially now when the cost of medical care is rising, and when interest in controlling that cost is mandatory.

Such technocracy can be expected to continue unless something is done to curb it. The implications are numerous. An analogous situation, not exaggerated greatly, would be a dictum outlawing the use of anticoagulant therapy on the basis of a series of 50 cases of acute myocardial infarction treated with anticoagulant in which 25 died. These events deserve the thoughtful concern of all physicians. The argument is not so much in favor of the use of pooled plasma as it is against the unscientific and arbitrary method of judgment that condemned it, with which all who are interested in the welfare of medical practice should be concerned.

How to get Paid for Treating Military Patients

Payment to civilian sources for emergency professional services rendered to military personnel, who are on active duty (as contrasted to retired, or inactive members of the National Guard or Reserve), is the responsibility of the surgeon of the geographical area in which such services are provided. Collection cannot be made from the Office for the Civilian Health and Medical Program for the Uniformed Services (OCHAMP-US), Denver, Colo., or its fiscal agents, who are responsible only for the payment of medical care rendered to authorized dependents and retired military personnel.

When a patient is identified as an Army member, on active duty, notification should be made immediately by telephone to the appropriate Army headquarters, as listed below, reporting where the individual is and the nature of the treatment required. The cost of the telephone call will be reimbursed with the other charges.

The Army headquarters will advise the caller about the administrative management of the patient, and how to submit the bills for service.

For elderly patients
in need of a mild tranquilizer
consider **Tybatran®**
brand of tybamate

(When you consult
the Prescribing Information
you may agree
it makes good sense)

PRESCRIBING INFORMATION

Indications: Tybatran (tybamate) has afforded symptomatic improvement in a variety of psychoneurotic disorders, especially in the treatment of the anxiety and tension components of psychoneuroses. Anxiety states manifested somatically have responded to Tybatran (tybamate).

Tybatran (tybamate) has been useful in the control of agitation in the aged and in the alleviation of some of the adverse emotional accompaniments of senility.

Tybatran (tybamate) has been used with benefit in the treatment of depressive symptoms associated with anxiety and other symptoms of psychoneuroses. However, it is not indicated for primary treatment of depressive states. It is not an antipsychotic agent, although it has been used as adjunctive therapy in some psychotic patients.

Dosage: One 350 mg. capsule, 3 times daily and two at bedtime is suggested as the adult starting dose. Adjust to suit individual requirements. Daily doses above 3000 mg. are not recommended.

Contraindications: Known hypersensitivity to tybamate. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings: Administer cautiously to patients receiving phenothiazines or other CNS depressants or having history of convulsive seizures (See Adverse Reactions). Consider possibility of additive actions with alcohol or other psychotropic agents, particularly phenothiazines or MAO inhibitors.

Precautions: Avoid abrupt withdrawal after prolonged use, although withdrawal symptoms have not been reported to date. Exercise caution in addiction-prone individuals. If symptoms of hypersensitivity occur, discontinue at once and initiate appropriate symptomatic treatment. Avoid activities requiring optimal mental alertness if drowsiness or vertigo are present. As with any new drug, use cautiously in patients with history of drug allergies, blood dyscrasias, and hepatic or renal disease; periodic measurements of hepatic, hematopoietic and renal function should accompany prolonged and/or high doses.

Adverse Reactions: Most frequent reactions, rarely requiring discontinuation of tybamate, include drowsiness, dizziness, nausea, insomnia, and euphoria. There have been a few reports of skin rash, urticaria, and pruritus. Rare side effects include hyperactivity, fidgetiness, flushing, and tachycardia, suggesting excessive stimulation; also ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis, and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients receiving tybamate (up to 6000 mg. daily) together with phenothiazines and other psychotropic agents, but not with tybamate alone. Consider the possibility of rare, serious adverse reactions such as may occur with the related drug, meprobamate. If excessive amounts are ingested, gastric lavage and symptomatic therapy, including central stimulants as necessary, are recommended. Before prescribing, consult package circular.

Supply: Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

The Maryland Council of Coca-Cola Bottlers

Rising Mental Health Demands, Innovative Programs and Budgetary Appropriations

George McK. Phillips, MD, FAPA
Superintendent
Crownsville State Hospital
Crownsville, Maryland

The average daily admission rate at Crownsville State Hospital has increased 54% over the past three years. This increase has been accompanied by an increase in releases of 101% during the same period, with a net decrease in the daily average inpatient population of over two hundred. Likewise, the budget has been increased 34.5%, most of which has been absorbed in meeting salary increases and rising operating costs.

This reduction in the daily average census is being accomplished by continuously building a positive mental health attitude towards the patients and towards mental illness itself, rather than by indiscriminate or inappropriate releases. Classification and prognostication of patients by diagnosis are being de-emphasized, except to meet medico-legal standards and broad treatment objectives, while intensive educational programs, aimed at the reorientation of all levels of the staff, are being stressed.

The hospital strives to reserve 24-hour inpatient hospitalization for protection of the patient and his family or the community, and when it is the only alternative for meeting specific therapeutic and rehabilitation requirements. As a result, a large number of persons, formerly kept in the hospital in custodial care 24 hours a day, now live in the community. Some are followed in day and evening care centers, and others in the hospital and other mental health outpatient clinics.

At the same time, consultants in family therapy and group psychotherapy visit the hospital one day a week, and conduct teaching conferences and workshops involving multi-disciplinary personnel at various levels of the administrative tree, in a simple, but effective, approach to reaching the hospital's objectives.

A pilot project, in which interested personnel and volunteers are trained as co-therapists and co-therapy aides in multiple family therapy, has been implemented and successfully operating for the past eighteen months. Psychiatric aides are also being trained to visit relatives and to work with families at home, as well as in the mental health clinics under supervision of professional personnel.

Staff previously confined to in-hospital assignments, working closely with county mental health clinic personnel, are taking on responsibilities for those community mental health programs which emphasize prompt, intensive and accurate evaluation of mental dysfunctions and the day to day living situations with which they may be associated. Existing personnel and facilities are utilized for providing evaluation, treatment, and rehabilitation services in the community. This orientation to providing mental health services has received little attention in past years—to some degree because of lack of funding, but mainly because of archiac attitudes towards the mentally ill, and rigid personnel role assignment.

Even if funds were available, a painful reality is that there is just not enough additional personnel with appropriate community orientation and expertise to meet the challenge of, and total demands for, mental health programs at the present salary levels. Change and expansion of roles of existing staff appear to be the most immediate avenue of optimism.

These changes are sometimes referred to as "innovative" at Crownsville. They are, in fact, a wider and more effective utilization of available personnel and facilities.

The hospital is constantly seeking ways to ef-

ficiently expand the role of existing personnel. As this continues, more personnel—professional and non-professional—are reoriented to thinking and acting "community" through appropriate educational programs. They are taking on those assignments in the community, germane to effective patient care in rehabilitation, in keeping with their change in orientation and increase in ability. Local and regional communities are also being oriented to thinking "self-sufficiency" through public education efforts, in order to create a receptive atmosphere for the "converted" hospital employee.

At the State level, it would be advantageous now to study in depth those hospitals which appear to be gaining the most mileage with what they have—not merely in terms of daily average inpatient census, but also, and perhaps primarily, in terms of admission and release rates, as well as extent and effectiveness of innovative projects. This evaluation should include existing hospital staff participation in providing mental health services in the community to the residents of its catchment area. Innovative programs of proven value should be supported and pushed across the board.

Funding should not be disallowed merely because of the decline in daily average inpatient population. The yardstick for changes in budgetary appropriations should be more appropriately based on the number of persons served and the treatment services offered; as well as the relative costs to the taxpayer for the various innovative approaches to providing needed mental health services. Should these factors not be considered, those community and other innovative mental health programs, which have a direct effect on inpatient population decline, would necessarily have to be curtailed. Unnecessary, inappropriate, and lengthy hospitalization would ensue and the hospital would be back where it started several years ago—a bulging, overcrowded and inefficient custodial human warehouse.

Tyson Street Open House to Benefit Eye Bank

More than a dozen colorful homes and attractive gardens of residents of the 800 and 900 blocks of Tyson Street, in downtown Baltimore, will be open to the public as features of the 19th Annual Tyson Street Open House on Saturday, June 7, as a special benefit project for the Medical Eye Bank of Maryland.

The Tyson Street community pioneered the restoration of Baltimore mid-city townhouses in 1946. It has been nationally recognized as a model area of the nation, and is one of the Baltimore landmarks illustrated in the current issue of Encyclopedia Britannica.

Many of the homes were built prior to 1800. They are believed to have been constructed as either slave quarters, or housing for laborers on the Bolton Estate which was northwest of Baltimore, when the town was incorporated in 1797. While the buildings have been enlarged and modified over the last century and a half, the area served as home for different classes of people over the years.

Just a century ago, Tyson Street was recognized as one of Baltimore's worst slum areas. It had formerly been known as one of the city's "bootlegger's rows," and at one time, the small houses were priced low enough to be purchased by former slaves with "freedom money."

In 1946, Edward Rosenfeld, who had already earned an international reputation as a creative artist, purchased a corner house for $3,000 to convert it into a studio and home. Within three years, the remaining 18 houses of the 900 block of Tyson Street, between Read Street and Park Avenue, had been purchased by persons who wanted to create a community of mid-city residences.

Over the past two decades many additions and modifications have been made to the homes, and today Tyson Street is the home address of attorneys, educators, librarians, doctors and representatives of other professions and skills.

Each year since 1950 the residents of Tyson Street have opened their homes to the public for general inspection, and a glimpse at some of the most colorful small gardens in Baltimore.

The influence of the 900 block Tyson Street has spread to the 800 block, and to nearby shops and residences in Baltimore's traditional "antique row." For a contribution of $2 per person to the Medical Eye Bank, more than a dozen homes and shops will be on view. All events will take place between 10:00 A.M. and 5:00 P.M., and funds will be used to further the research and service activities of the world's largest organization securing eyes for cornea transplantation, and ocular research purposes. For tickets and detailed information, please contact the Medical Eye Bank of Maryland, 22 W. Franklin Street, Baltimore, Maryland 21201, or phone 539-4353.

AMA Surveys

Physicians engaged in the group practice of medicine comprised 10.9% of all doctors involved in patient-care activities in 1965, according to a recent statistical study made by the AMA's Department of Survey Research.

"Group medical practice," as defined by the AMA Council on Medical Service, "is the application of medical services by three or more *full-time* physicians formally organized to provide medical care, consultation, diagnosis, and treatment through the joint use of equipment and personnel, and with the income from medical practice distributed in accordance with new methods previously determined by members of the group."

The survey views the group practice of medicine as "a significant force in the health care system."

Of the 4,289 medical groups responding to the AMA survey, 2,161 (50.4%) were single-specialty groups; 651 (15.2%), general practice groups, and 1,477 (34.4%), multi-specialty groups.

The group physician complement numbered

Group Practice

28,381, of whom 25,452 were on a full-time basis.

The survey reported 88 groups utilizing a prepayment mechanism as part of, or all of, the group activity. "Most of the prepaid groups (88.6%) were multi-specialty groups, and almost all of the physicians in prepaid groups (98.5%) were in multi-specialty groups," according to the survey.

Physicians affiliated with prepaid group practices numbered 3,491, 71.1% of whom were in the general specialties.

"Of the 31 (35.2%) prepaid groups which reported an affiliation, nine were associated with hospitals, only one with a medical school, and six were associated with a labor union, employee association, or consumer cooperative. The remaining 15 prepaid groups reported affiliation with 'other' organizations. No prepaid group reported an affiliation with industry."

Three of the 29 states, where prepaid group practices were found, contained 44.3% of the prepaid groups, and 71.7% of the physicians. The three states were California, Minnesota, and New York.

GREENBERRY WOODS

NORTHERN PARKWAY AT JONES FALLS EXPRESSWAY

Now When You Recommend Moist Heat,

Recommend Automatic Moist Heat.

Until now, application of moist heat required boiling water, hot towels, and somebody to apply them. The Battle Creek THERMOPHORE changes all that. It provides instant and automatic moist heat, intensely hot, deeply penetrating.
The patient simply plugs it into an outlet. This unique hot fomentation pad then generates its own moisture from the air. Intensely hot moist heat is constantly maintained, and evenly distributed throughout the pad. No water is needed, no filling or emptying is required.
Large 13" x 27" pad covers back, or chest and abdomen, or both legs. Safety thermostat turns it off automatically, prevents overheating.
Price is **$35.00.** Also available in medium size 13 x 13 **$25.00.**

Physicians Questioned on Heart Transplants

The majority (55%) of physicians questioned in a Playback Poll by Marion Laboratories said that they would *not* consent to a heart transplant on themselves even if they had advanced heart disease with a poor prognosis.

Only 27% of the respondents indicated that they would consent to such transplant surgery, while 18% were undecided.

Playback posed this same question to the physician panel. At that time less than a majority of respondents (42%) said they would not consent to transplant surgery, while 36% said that they would say yes. Six months and more than 20 transplants later, the appeal of such surgery to the Playback physician appeared to be lessening.

Among cardiologists, 17% said they would consent to transplantation now (27% said yes six months prior), while 63% said they would not consent (53% said no when previously questioned).

The statistics revealed that positive opinion toward transplant surgery is directly related to the age of the doctor. Physicians under 35 years voted 35% in favor of transplant, 44% against; in the 35-50 age bracket, opinion was 26% in favor, 54% against; in the 50-64 category, opinion was 25% in favor, 58% against.

The most significant switch in opinion during the six-month period was in the group of doctors over 65. Earlier 36% would have accepted a transplant, six months later only 24% would. When first questioned, 49% would not have accepted a transplant, later 71% said no. Earlier 15% were undecided, but later the undecided comprised 2% of the respondents.

Some of the physicians' reasons for not accepting such surgery included:

"Rejection will be 100%"

"It is not a practical solution. At present it is surgical exhibitionism"

"Not at this time. Results too poor."

Multiphasic Screening

The value of a periodic health examination has long been stressed. Now, more than ever before, persons in presumably good health are encouraged to have an annual "check up." But a thorough examination, including X-rays and laboratory tests, is time consuming and costly. For the medical profession, the improvement of health care for all people is a constant challenge, yet the limitations of time, money, and manpower are always present.

A plan to cope with these conditions is the development of multiphasic screening programs. These may be described as automated multi-test laboratories where test procedures, which include X-rays, electrocardiograms, visual and hearing acuity tests, blood pressure readings, glucose tolerance, complete blood testing and medical questionnaires, are administered. The data from all tests is recorded on punch cards and fed into a computer which produces a report on each individual. The purpose of screening is to sort apparently "well" persons into two groups.

1. Those having abnormalities indicating the characteristics of a certain disease.
2. Those not possessing abnormalities outside the pale of normal health.

The computerized health protection center is not a substitute for periodic physical examination or any other traditional health care. The tests are designed to be evaluative, and are intended to alert the physician to areas requiring diagnostic attention.

The United States Public Health Service now has four demonstration projects for multiphasic screening, three of which are operative and one under development. The objectives of the PHS centers are, "The development of a model, high-quality health maintenance system for a defined urban population, using automated equipment, and techniques for screening, and incorporating the principles of health counseling, referral and follow-up to insure subsequent physical examination by the participant's own physician. The ultimate goal is to decrease mortality and morbidity through early disease detection and intervention."

The four PHS centers are located in Milwaukee, New Orleans, Brooklyn, and Providence, Rhode Island (opened in January 1969). At the Brookdale Center in Brooklyn, the most populated of the four areas, they hope to screen 10-15,000 people in the first year.

The precedent for these multi-test centers comes from the Kaiser Foundation Hospital in Oakland, California which began its screening program in December 1966. There is also a private screening center in Southfield, Michigan and, through the Regional Medical Programs, Missouri, Tennessee, and the Rochester, New York area are launching large-scale screening programs.

Though services in the PHS centers are free to patients, the cost of screening is now $40 per person with $25 per person as a goal in all centers. This is compared with $85 per person charged by the Michigan center or $200, if similar tests were ordered by a private physician.

Dr. Morris F. Collen, Chief of Staff at the Kaiser Foundation Hospital has suggested that the automated lab can operate most efficiently as part of a medical center with inpatient and outpatient services. He suggests that hospitals in communities of 100,000 or more will be affiliated with an automated laboratory for admission, preoperative, and periodic health examinations. The labs will probably be connected with a regional computer center providing data processing by telephone lines.

Dr. Frederick C. Swartz, in a statement to the U.S. Subcommittee on Health of the Elderly in September, 1966, and the AMA Council on Medical Services, in their report (D. A-68), presented both benefits and limitations of the concept of multiphasic screening. They found that the plan would provide economic health appraisal to large numbers of the adult population who might not otherwise receive health care. It would also relieve the acute medical manpower shortage by conserving physicians' time. On the other hand, it may create depersonalization of health care, and false security or unnecessary anxiety by issuing a report to a patient without adequate physician follow-up.

The PHS and the AMA both acknowledge that

study and analysis of the automated multi-test system are imperative. Controlled trials should be given in many settings where continuous evaluation and revision of tests, for suitability to the population, would take place. More accurate data is needed to determine what constitutes "normal" conditions, and there is a need to study the long range possibilities for disease prevention, not just detection. The real impact of multiphasic screening on medical manpower and cost conservation must be studied carefully. Moreover, successful incorporation into the community health service structure and cooperation by local physicians to insure follow-up consultation whether reports are negative or positive is essential.

The AMA report calls multiphasic screening a promising technique. Dr. Swartz believes it to be a major field of medicine of the future and a major challenge of today. It could well provide an answer for the patient who asks, "How well am I?", "Could I run a block?", "Could I run a mile?", "Could I handle a job with added responsibilities and pressures?".

Transplants Discussed at First Renal Seminar

"Physicians should be concerned with prolonging personality rather than just a biochemical system," stated Dr. Alfred B. Starratt, rector of Emmanuel Episcopal Church, at a seminar on the moral, legal, and medical aspects of organ transplants and kidney dialysis held at the University of Maryland School of Medicine.

The seminar was the first of eight on renal disease that are being held this year at the medical school. They are being sponsored by the Maryland Kidney Foundation and arranged by Glenn Lubash, MD, associate professor and head of the division of renal diseases and hypertension.

"As more is learned about a disease," Dr. Starratt said, "the more responsibility a doctor has to tell his patient the prognosis and diagnosis of his illness. No one wants to live as a vegetable."

The other participants were David Thompson, MD, professor at Cornell Medical School and director of the New York Hospital, and John F. King, legal advisor to the Maryland Medical and Chirurgical Faculty, and a member of the Governor's Joint Commission on Organ Transplantation. Samuel T. R. Revell, MD, professor of medicine, moderated.

Dr. Thompson raised the question of where the huge sums of money needed to save the lives of kidney patients will come from. He said that the majority of patients are treated by dialysis, although more transplants are being performed, and that the costs for care may rise to $500 million a year. He believes that federal funds may be the answer, and that ideally, the regional medical programs could set up facilities.

Mr. King discussed the Maryland Anatomical Gifts Law, passed in May 1968, which authorizes physicians to make transplants from cadavers and live donors. He said that Maryland's law is one of the first and may become a model for other states.

Information for Authors

MANUSCRIPTS: Manuscripts will be accepted for consideration for publication with the understanding that they are original, have never before been published, and are contributed solely to the Maryland State Medical Journal.

All manuscripts are acknowledged upon receipt and are followed up by notification of either acceptance or rejection. Rejected manuscripts are returned by regular mail. Accepted manuscripts become the property of the Journal and are not returned. The Journal is not responsible for loss of manuscripts through circumstances that are beyond its control.

Manuscripts should be addressed to: Editor, Maryland State Medical Journal, 1211 Cathedral St., Baltimore, Md. 21201.

SPECIFICATIONS: Manuscripts must be original typed copy, doublespaced throughout (Including text, case reports, legends, tables and references) with margins of at least 1½ inches. Pages should be numbered consecutively.

The manuscript should include the title (brief and concise), the full name of the author (or authors) with degrees, academic and professional titles, affiliations, and any institutional or other credits. Please include a complete address where the author may receive proofs of his article for his approval and corrections.

All manuscripts should be accompanied by a carbon or Xerox copy and the author should retain another copy for his records.

TABLES: Each table should be typed on a separate sheet of paper, be numbered, have a brief descriptive title, and its position in the text should be indicated.

Be sure that statistics are consistent in both tables and text.

REFERENCES: References should be limited to those citations noted in the text, and kept to a minimum of 18. (A complete review of the literature is rarely desirable.) The references must be typed, doublespaced, and are to be numbered consecutively as they appear in the text, with their positions in the text indicated. An alphabetized bibliography is used only when the listing is of books suggested for supplementary reading.

All references must be checked for absolute accuracy. Each journal reference must include author(s) and initials, complete title of article, name of publication, volume, first page of article, and date. Complete dates (month, day, and year) are to be included with all references that have appeared within the last three years. Include with book references name of author(s) and/or editor(s) with initials, title of book, edition, location, publisher, year, volume (if given), and page. If reference is to a chapter within a book, include the author of the chapter (if different from author of the book), and the title of the chapter, if any.

ILLUSTRATIONS: Authors are urged to use the services of professional illustrators and photographers when possible. Drawings and charts should always be done in black ink on white paper. Clear, glossy photographs, black on white, should be submitted and such illustrations numbered consecutively and their positions indicated in the text.

Magnifications will be modified in proportion to the amount of reduction necessary to fit the pages of the Journal. Please do not deface an illustration by writing on the front or the back, nor should it be taped or pasted to paper. The illustration may be pasted onto a piece of cardboard. Attached to the back of each illustration, chart or photograph should be the figure number, the author's name and the title of the article.

Legends for illustrations should be typewritten on a separate page with numbers corresponding to those on the photographs and drawings.

Recognizable photographs of patients are to be masked and should carry with them written permission for publication.

EDITORIAL RESPONSIBILITY: Manuscripts are subject to editorial modification and such revisions as are necessary to bring them into conformity with Journal style.

Statements made or opinions expressed by any contributor in any article or feature published in the Journal are the sole responsibility of the author.

PERMISSIONS: When material is reproduced from other sources, full credit must be given to both the author and publisher and written permission from these sources must be included when the material is submitted.

COPYRIGHT: Material that is published in the Maryland State Medical Journal is protected by copyright and may not be reproduced without the written permission of both the author and the Journal.

from the discord of anxiety...

to emotional harmony

with the aid of antianxiety

Librium®
(chlordiazepoxide HCl)
5-mg, 10-mg and 25-mg capsules

In an age of swift change and challenge, susceptible individuals may experience varying degrees of excessive anxiety. The resulting emotional stress may precipitate significant functional disorders or complicate existing organic disease. In properly individualized maintenance dosage, Librium (chlordiazepoxide HCl) quickly helps relieve anxiety and apprehension, provides useful adjunctive therapy in psychophysiologic disorders—yet seldom impairs mental acuity or ability to function. Librium has demonstrated a wide margin of safety in short- and long-term therapy.

Also available:
Libritabs®
(chlordiazepoxide)

ROCHE
Roche
LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

Before prescribing, please consult complete product information, o summary of which follows:
Indications: Indicated when onxiety, tension ond apprehension ore significont components of the clinicol profile.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Coution potients obout possible combined effects with olcohol ond other CNS depressants. As with all CNS-octing drugs, caution potient against hozardous occupations requiring complete mental alertness (e.g., operating mochinery, driving). Though physicol and psychological dependence have rorely been reported on recommended doses, use caution administering to addiction-prone individuols or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug ond similar to those seen with barbiturotes, have been reported. Use of ony drug in pregnancy, loctotion, or in women of childbearing oge requires that its potentiol benefits be weighed agains its possible hozords.
Precautions: In the elderly and debilitated, and in children over six, limit t smollest effective dosoge (initially 10 mg or less per day) to preclude ata or oversedation, increosing gradually os needed and toleroted. Not recommended in children under six. Though generally not recommended, combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiat drugs such os MAO inhibitors and phenothiazines. Observe usual precoutions in presence of impaired renol or hepatic function. Paradoxical reoctions (e.g., excitement, stimulation and ocute roge) have been reported in psychiotric potients ond hyperactive oggressive children. Emp usual precoutions in treotment of onxiety stotes with evidence of impending depression; suicidol tendencies moy be present and protective measur necessory. Varioble effects on blood coagulation have been reported ver rorely in potients receiving the drug ond oral onticoogulonts; causol relationship hos not been estoblished clinicolly.
Adverse Reactions: Drowsiness, otaxio ond confusion moy occur, especial in the elderly ond debilitated. These ore reversible in most instances by proper dosage odjustment, but are olso occasionally observed at the low dosage ranges. In o few instances syncope hos been reported. Also encountered ore isoloted instonces of skin eruptions, edemo, minor menstru irregularities, nauseo ond constipation, extropyromidal symptoms, increc and decreased libido—oll infrequent ond generally controlled with dosag reduction; chonges in EEG patterns (low-voltage fost activity) moy oppea during and after treatment; blood dyscrosios (including agranulocytosis), joundice ond hepotic dysfunction hove been reported occasionally, maki periodic blood counts and liver function tests advisoble during protractec therapy.

LACTINEX®

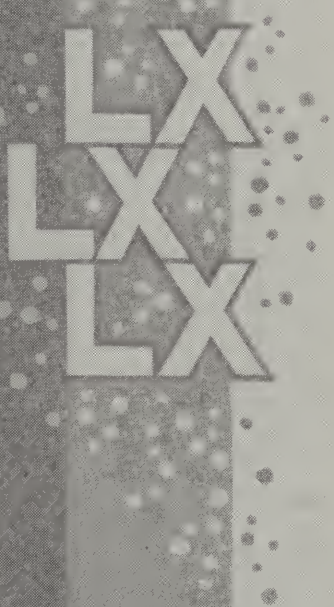
TABLETS & GRANULES

■ **to help restore and stabilize the intestinal flora**

■ **for fever blisters and canker sores of herpetic origin**

Lactinex contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

Lactinex has been shown to be useful in the treatment of gastrointestinal disturbances, and for relieving the painful oral lesions of fever blisters and canker sores of herpetic origin.[1,2,3,4,5,6,7,8]



No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

b.i.d.

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appro measures should be taken.

In infants, increased intracranial pressure with bulging fontane been observed. All signs and symptoms have disappeared rapidly cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting rhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—macu ular and erythematous rashes; a rare case of exfoliative dermatit been reported. Photosensitivity; onycholysis and discoloration nails (rare). Kidney—rise in BUN, apparently dose related. Tra increase in urinary output, sometimes accompanied by thirst (Hypersensitivity reactions—urticaria, angioneurotic edema, anaph Teeth—dental staining (yellow-brown) in children of mothers give drug during the latter half of pregnancy, and in children given th during the neonatal period, infancy and early childhood. Enamel plasia has been seen in a few children. If adverse reaction or i crasy occurs, discontinue medication and institute appropriate th

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Sho given 1 hour before or 2 hours after meals, since absorption is im by the concomitant administration of high calcium content drugs and some dairy products. Treatment of streptococcal infections continue for 10 days, even though symptoms have subsided.

Editorial—Your Pathologist is a Practicing Physician Like Yourself—Be Loyal to His Local Laboratory, John F. Schaefer, MD **60**

Occipital Neurectomy in the Treatment of Headache—Results in 30 Cases, J. Peter Murphy, MD **62**

"The primary treatment of any headache problem is, and properly should be, medical management. If a therapeutic response is not prompt and satisfactory, the next step is to investigate further whether or not an intracranial source of the chief complaint exists. . . . Psychic conflict and repressed aggression are so well recognized to be a competent producing source of pain in the cranial or cervical regions that expressions such as "a real headache" or a "pain in the neck" are used in all languages to describe or refer to situations or associations which inspire frustration, antagonism, or rage. It is my belief, however, that the concept of "tension headache" has been so widely and thoroughly oversold that many patients are denied the opportunity to obtain effective relief from headache-producing cranial or cervical neuralgias by surgical means."

Diamonds Come In Many Shapes

A unique shape diamond in its appropriate mounting creates a remarkably different and most unusual ring.

Besides the round, there are heart shapes, emerald cut, pear shapes, crescents, marquise, half moons, tapered, square cut, baguettes, etc.

We'd like you to see these out-of-the-ordinary diamonds.

DEADLINE FOR RESOLUTIONS

The deadline for resolutions to be considered at the Semiannual Meeting of the Faculty is:

FRIDAY, JULY 11, 1969

Any resolutions must be in the Faculty office by 5:00 p.m. on that date.

The Reference Committee meeting during which any resolutions will be discussed, is scheduled for:

THURSDAY, AUGUST 14, 1969

at 7:30 p.m.

ECONOMIC FACTS OF LIFE

A recent study, completed by the Association of American Medical Colleges, indicates that salaries of full-time faculty at schools of medicine range from a low of $18,000 in pediatrics to a high of $40,000 in surgery (as chairman).

Low figures apply to assistant professorships. The highs refer to department chairmen. Listed by specialty the salaries are:

Anesthesiology	$25,000	$36,800
Medicine	19,000	36,000
Obstetrics-Gynecology	20,000	36,000
Pathology	19,200	34,400
Pediatrics	18,000	35,000
Psychiatry	20,000	35,900
Radiology	25,000	40,000
Surgery	22,000	40,000

Union plumbers in Philadelphia recently were given a new contract which raised their hourly wage to $9.76; or a total of $19,520 for a 40 hour work week.

In San Francisco, plumbers recently negotiated a new contract to raise their hourly rate to $10.65.

MED-CHI SEMIANNUAL MEETING

A program of interest, both scientifically and socially, to physicians and their families has been scheduled at the HOTEL HERSHEY on THURSDAY, FRIDAY, AND

MED-CHI SEMIANNUAL MEETING (cont'd)

SATURDAY, SEPTEMBER 4, 5 and 6. (See elsewhere in the Journal for further information about the program and a hotel reservation form.) MAKE YOUR RESERVATIONS NOW!

SCIENTIFIC EXHIBITS FOR 1970

The Committee on Program and Arrangements of the Medical and Chirurgical Faculty is interested in obtaining scientific exhibits from members for displa at the 1970 Annual Meeting, April 1, 2 and 3, in Baltimore. Contact the Faculty office for further information.

FACULTY INSURANCE PROGRAMS PAY OFF

Members of the Faculty's Insurance Programs receive welcome news recently when it was announced that benefits would be broadened and premiums reduced, at the same time.

The increase in benefits includes:

Major Medical Maximum Benefit is now up to $20,00

Daily Private Room limit has been raised to $60.

Co-insurance increase now covers up to 90%

Automatic additional life insurance for members and dependents

The rate reduction, scaled by age groups, would var with the coverage carried by the physician.

GENERAL MEETING ON INCORPORATION

A general meeting for Faculty members, their legal advisers and tax consultants, has been set to discus the recently enacted Incorporation of Self-Employed Persons Act.

It will be held at the Faculty building on

TUESDAY, JUNE 24, 1969, at 7:30 p.m.

No reservations are required.

AMA Prepares Position Papers On Reasonable Charge Criteria

Implementation of proposed changes for determining reasonable charges under the Medicare Part B program "would impair existing relationships between Part B carriers, physicians and government," said Ernest B. Howard, MD, Acting Executive Vice President of the American Medical Association, in a recent letter to HEW Secretary Robert H. Finch.

SSA Directive

The Social Security Administration, in a December 17th instructional letter to the Part B carriers, categorically stated that, "Prevailing charge limits should be established by calculating the mean of the customary charges for a given service and adding one standard deviation above the mean (rounded out to the nearest dollar), or the equivalent."

Position Papers

The AMA Council on Medical Service, Dr. Howard noted, is in the process of preparing position papers on six specific subject areas relating to the directives. They are:

—Determination of reasonable charges for physicians' services—interrelationship to usual, customary and reasonable fees and to prevailing fees concepts.

—Procedures relating to development and application of (a) physicians' fees profiles, and (b) screen of prevailing charges in area.

—Considerations involved in submitting charges for physicians' services—itemized billing, all-inclusive charges billing, direct billing and assignments.

—Charges for services obtained from an independent laboratory.

—Charges for physicians' services in teaching institutions—patterns employed to distinguish between patient care and teaching activities.

—Peer review of physicians' fees and utilization of health care services.

The Council intends to use the position papers, supplemented by information obtained in discussions with the carriers, as the basis for consultation with Secretary Finch and other HEW officials.

The Council held a meeting on March 27 with members of the Blue Shield Government Programs Committee to obtain their views on these subjects.

Vaginal Contraceptives

Far from having "historical interest only" in the age of oral contraception, other methods of birth control deserve careful consideration in patients for whom orals are inadvisable. . . . Physicians should not have an orals-or-nothing attitude toward family planning because many of the other contraceptive methods have improved "remarkably" of late, and can provide excellent protection when carefully used.

These are among the major points made in a symposium held recently at The Johns Hopkins University School of Medicine. "Vaginal Contraception In The Era of the Pill" was the subject of the conference, sponsored by Ortho Pharmaceutical Corporation.

"We have two methods which provide the potential for meeting the threat of overpopulation—oral contraception and the intrauterine device," said Nicholson J. Eastman, MD. But the Professor of Obstetrics Emeritus at Johns Hopkins added, that for the minority of women unsuited to such regimens, "something must be done to provide alternate methods of conception control."

Three fourths of women discontinuing orals return to methods they used previously, according to Charles F. Westoff, PhD, professor of sociology at Princeton University. Many of the others turn to contraceptive foam, a method even newer than the pill.

"There are various methods available at the present time," said Aquiles J. Sobrero, MD, director of the Margaret Sanger Research Bureau in New York. "Many, especially the jellies and cream, have improved remarkably in efficacy in the last ten years. We also have a brand-new method—foam—which is very much 'in.'"

Dr. Sobrero called it "distressing" that "so few data are available on the effectiveness of the diaphragm. . . ." But Dr. Westoff told the conference at Johns Hopkins that "if properly inserted and

Still Essential, Symposium Informs

properly used, the failure rate of the diaphragm is practically zero."

Diaphragms are "still the best method for private patients who do not want or cannot use the pill," added Herbert H. Thomas, MD, clinical associate professor of obstetrics and gynecology at the Medical College of Alabama. And Georgeanna Seegar Jones, MD, associate professor of gynecology and obstetrics at Johns Hopkins, agreed that when diaphragms are fitted properly—and patients instructed in their use—they offer almost 100% effectiveness.

Ideally, there should be "a total contraceptive program," said Dr. Sobrero, so that women do not feel "afraid to come back and displease the doctor" by admitting they are dissatisfied with the pill. "But first, it is necessary to bridge the gap between the doctor and patient, and get the woman to take the initiative and ask for birth control information. Then it is necessary to overcome the indifference of many doctors about recommending birth control or devoting the necessary time to this health measure."

Age also can be an important factor in conception control, the symposium brought out. The older patient is more likely to discontinue the pill than is the younger, and the age of the physician may influence the contraceptive method selected.

"Part of the problem lies in our medical schools," declared Dr. Thomas. "They should be encouraged to teach all methods of contraception. Another educational medium which I think should be encouraged is the lay press. Articles favorable to vaginal contraception will help inform women about adequate contraception and also encourage doctors to learn about types of contraceptives other than the pill.

"Both the public and the medical profession need to be educated about methods of birth control other than oral contraceptives. In the final analysis, it is the degree of patient and doctor motivation, along with proper instruction of the patient, that determines effectiveness," he stated.

LUNG CANCER, A STUDY OF FIVE THOUSAND MEMORIAL HOSPITAL CASES, William L. Watson, MD; The C. V. Mosby Company, St. Louis, 1969.

While William L. Watson, MD, is listed as the author of this publication, it was co-authored by many distinguished and well-known specialists in the field of cancer and cancer research. Its aim is to present, in a reasonable space and accessible form, the main features of the origin, structure, natural history, and modern treatment of lung cancer.

The concepts, as well as the guidelines described, differ considerably from those in other publications on the same subject. The data on this one anatomic form of cancer have been accumulated during the past 40 years at the Memorial Hospital, New York city. Each of the many facets of the lung cancer problem is reported by a specialist in his own field, yet a certain homogeneity is provided by the fact that each writer is a member of the same medical center, and each is well grounded in the general field of oncology.

This study of 5,000 cases of lung cancer makes it possible to take the somewhat advanced position that cell type is of the greatest clinical importance in regard to the life history, etiology, prognosis, and form of treatment.

This is a book well worth reading, and adding to your medical library.

COLLATERAL CIRCULATION IN CLINICAL SURGERY, D. E. Strandness, Jr., MD; The W. B. Saunders Co., Philadelphia, 1969.

The purpose of this book is to discuss, in detail, diseases in which a consideration of collateral circulation is important. In most instances, these diseases are involved in the development of collateral circulation.

In each area considered, attention is devoted to normal anatomy, congenital variations, and the available collateral pathways. These discussions include the consideration of the signs and symptoms pertinent to disease location and collateral circulation. Methods of evaluation and interpretation are stressed; and application of modern study techniques is covered in detail wherever applicable.

This book is designed for the experienced physician, vascular surgeon, and surgical specialist, as well as the house officer.

DIAGNOSIS AND MANAGEMENT OF PAIN SYNDROMES, Bernard E. Finneson, MD; The W. B. Saunders Co., Philadelphia, 1969.

Six years have elapsed since the first publication of this volume, and enough changes have taken place to warrant a reworking of the text. However, most of the changes incorporated into this book, and the techniques described, are widely accepted and no claim is made for original methods or any "new concept".

A number of the techniques fall solely within the discipline of neurosurgery and are not intended as an inducement to those not trained in this field. An appreciation of the available operative procedures is helpful to anyone involved in the management of pain.

CURRENT THERAPY, 1969, Howard F. Conn, MD, and other consulting editors; The W. B. Saunders Co., Philadelphia, 1969.

This volume marks the beginning of the third decade of publication of Current Therapy. It is assumed that physicians using this volume have intimate knowledge of the detailed information available in the official product circular for each drug before prescribing the drug for their patients.

The therapeutic action of most drugs mentioned is under continuous clinical evaluation and, from time to time, new uses, changes in dosage, the appearance of unexpected contraindications, and adverse reactions are reported. The articles have been written by physicians prominent in their respective fields, and represent a careful distillation of the vast amount of information available to the therapist today.

The fact this publication has been published and used for 20 years, should indicate its usefulness to all.

his ulcer did not heal...until its surface was cleared of dead tissue and debris

FIRST APPLICATION
ELASE Ointment is applied to a deep ulceration of a finger.

EIGHTEEN DAYS LATER
Healing has progressed rapidly without interruption or interference from any accumulated purulence or necrotic tissue. Greatly reduced size of lesion and minimal scar tissue indicate quality and vigor of healing which is almost complete.

to aid in debridement to facilitate healing in chronic cutaneous ulcers...

Elase® Ointment

(fibrinolysin and desoxyribonuclease, combined, [bovine] ointment)

PARKE-DAVIS

By helping to remove dead tissue and debris from the ulcer's surface, ELASE Ointment creates a better environment for the elimination of infection, for healthy granulation...*for healing.* Its lytic enzymes effectively break down DNA in dead leukocytes and other debris...the fibrin in blood clots, serum, and purulent exudates...and the denatured proteins in necrotic tissue. Protein elements of *living* tissue are relatively unaffected. ELASE Ointment is indicated in stasis ulcers and in other infected or inflamed ulcers caused by circulatory disturbances. In cases requiring skin grafting, it is used preoperatively for debridement. For ambulatory patients debridement with ELASE Ointment is a convenient therapy and a regimen likely to be followed. *Precautions:* Observe usual precautions against allergic reactions, particularly in persons with a history of sensitivity to materials of bovine origin or to mercury compounds. *Adverse Reactions:* Side effects attributable to the enzymes have not been a problem at the dose and for the indications recommended. *Discussion:* Successful use of enzymatic debridement depends on several factors: (1) dense, dry eschar, if present, should be removed surgically before enzymatic debridement is attempted; (2) the enzyme must be in constant contact with the substrate; (3) accumulated necrotic debris must be periodically removed; (4) the enzyme must be replenished at least once daily; and (5) secondary closure or skin grafting must be employed as soon as possible after optimal debridement has been attained. It is further essential that wound-dressing techniques be performed carefully under aseptic conditions and that appropriate systemically acting antibiotics be administered concomitantly if, in the opinion of the physician, they are indicated. *Available:* ELASE Ointment is supplied in 30-Gm. tubes containing 30 units (Loomis) of fibrinolysin and 20,000 units of desoxyribonuclease with 0.12 mg. thimerosal (mercury derivative); and in 10-Gm. tubes containing 10 units of fibrinolysin and 6,666 units of desoxyribonuclease with 0.04 mg. thimerosal. ELASE Ointment has a special base of liquid petrolatum and polyethylene; contains sodium chloride and sucrose used during manufacture; is stable at room temperature through the expiration date stated on the package.

When it's more than a bad cold

your patient can feel better while he's getting better

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In tetracycline-sensitive bacterial infection complicating respiratory allergy, ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Contraindications: Hypersensitivity to any component.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Drowsiness, anorexia, slight gastric distress can occur. In excessive drowsiness, consider longer dosage intervals. Persons on full dosage should not operate vehicles. Nonsusceptible organisms may overgrow; treat superinfection appropriately. Treat beta-hemolytic streptococcal infections at least 10 days to help prevent rheumatic fever or acute glomerulonephritis. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Adverse Reactions: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity* reactions—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

Lederle

348-8

Novahistine® LP decongestant

(Each tablet contains 25 mg. of phenylephrine hydrochloride and 4 mg. of chlorpheniramine maleate.)

DOW

THE MONTH IN WASHINGTON

Health, Education and Welfare plans to impose Blue Shield schedules for physicians under Medicaid, and to limit payments to hospitals under Medicaid and Medicare, drew strong responses from the American Medical Association and the American Hospital Association.

Dwight L. Wilbur, MD, president of the AMA, urged in a letter to Robert H. Finch, HEW Secretary, that all segments of the health care field be consulted in effecting economies in government-paid health services.

"The American Medical Association is eager to make available to your office the composite experience and judgment of the nation's physicians, who are the principal providers of health care to all the people," Dr. Wilbur said. "The needs and problems of patients in all walks of life, at all income levels, come to their attention, in composite, more than a billion times a year.

"It has always been a principle of both the humanity and the professional code of the physician that no one shall ever be denied quality health care because of his inability to pay. The present concern is how this universal care can best be provided within a viable economic system and in the face of burgeoning demand for medical manpower, services, and facilities. . . .

"The knowledge and judgment of the nation's physicians —as well as of the prepayment plans, health insurance industry, hospitals, the allied health professions, the actuaries and others —must be enlisted in your battle against the health-care portion of the inflation problem."

Dr. Wilbur wrote Finch following the HEW announcement that federal spending on the Medicaid-Medicare programs would be trimmed by $328 million through imposing Medicaid fee schedules based on prevailing Blue Shield rates, limiting mental illness benefits under Medicaid, and cutting down hospital overhead allowances in Medicaid and Medicare.

"It is important to recognize that there are many variables in the circumstances of payment for medical and hospital services," Dr. Wilbur stated. "Local needs and resources, the educational and motivational levels of the people, the economic conditions of the state and the community are among the reasons for the differences exhibited by the payment patterns of the Blue Shield plans and health-insurance companies.

"These circumstances must be the foundation for any policies involving cost and payments. No universal pattern—no matter how many variations it may try to provide—can be imposed on the thousands of localities without wreaking havoc and probably increasing inefficiency and costs."

Concerning the imposition of Blue Shield rates as fee schedules under Medicaid, Dr. Wilbur warned, in an address before the American Society of International Medicine in Chicago, that a later step "might be that of physicians, in groups, being placed on salary, and, therefore, abandoning the fee-for-service principle." He said that physicians, in combatting such government efforts, must accept the major responsibility of keeping fees as moderate as possible.

The American Hospital Association protested, in a letter to President Nixon, against removal of the 2% overhead allowance for hospitals. Officially representing the AHA, Ray R. Eppert, a hospital trustee from Detroit, said in a memorandum accompanying the letter to Nixon:

"The recent announcement of a reduction in Medicare reimbursement poses a serious threat to institutional integrity and, therefore, to the ability of hospitals to serve the sick and injured of this nation. Hospitals have been repeatedly assured, at the highest levels of government, that Medicare changes would not be made without consultation with their designated representative, the American Hospital Association.

"The AHA has tried repeatedly, but unsuccessfully, to meet with Secretary Finch. It is incredible that the federal government would propose, without any consultation, removal of the 2% allowance which is a proper component of reasonable costs guaranteed under the law as passed by the Congress.

"The department apparently deemed it unnecessary to consult with the hospital field, and, as far as can be determined, made no serious study of the effect of the proposed reduction on hospitals. Payment of nothing but raw costs will lead . . . to the serious underfinancing of our hospitals."

* * *

Drug combinations became the target of the Senate Small Business Subcommittee's investigation of the prescription drug industry.

Medical school professors, critical of drug combinations, were called as witnesses in two days of hearings opening this phase of the drug industry probe which began nearly two years ago. It was not indicated when, or even whether, drug company representatives would have an opportunity to defend their combination products before the subcommittee.

Dr. Heinz F. Eichenwald, MD, a National Academy of Science drug specialist, and pediatrics chairman, University of Texas Southwestern Medical School, told the subcommittee that "misleading advertising" had lured "the gullible physician" into prescribing useless, and sometimes dangerous, drug combinations. He also said continued use of drug combinations "amounts to a strong indictment of the ability of many physicians to judge what is effective and what isn't."

Dr. Eichenwald and William M. M. Kirby, MD, a medical professor at the University of Washington Medical School in Seattle, testified on combination drugs on the opening day of hearings conducted by the subcommittee headed by Sen. Gaylord Nelson (D., Wis.).

The two physicians were among 30 drug experts who evaluated combination drugs for the National Academy of Science. The experts' unanimous report said the combinations were useless and sometimes dangerous.

The report caused the U.S. Food and Drug Administration to serve notice April 2, that the 78 combination drugs studied by the scientists would be banned from the market unless drug makers could prove the Academy studies were wrong. In many cases, drug companies are fighting the FDA order.

Eichenwald and Kirby both testified that physicians are widely prescribing the combinations despite numerous warnings of their potential danger.

Eichenwald said drug firms point to the admittedly widespread use of combinations to state that physicians must therefore have demanded them.

"The opposite is true," Eichenwald's prepared testimony said. "The demand was created by misleading advertising."

In another action, Nelson, D-Wis., urged the FDA to restrict cyclamate-sweetened products to a prescription-only basis.

In a letter to FDA, Nelson said "tens of millions of children and adults across the nation are unwittingly being exposed to potentially serious health hazards by the unnecessary consumption of cyclamate-sweetened soft drinks, cereals, desserts and 'sugar'-coated pills."

He added, "increasing scientific evidence indicates that cyclamates can cause chromosome breakdown, the birth of undersized offspring in animals, interference with effectiveness of certain antibiotics, persistent diarrhea, liver diseases, skin irritation and eruption, difficulty with blood clotting, and high blood pressure."

Cyclamate was originally developed as a sugar substitute for diabetics and others forced to restrict their intake of sweets. The FDA recently proposed regulations on labelling and ingredient content for cyclamate, often used now as a general substitute for sugar.

* * *

The Joint Commission on Mental Health of Children is recommending a broad program aimed at bettering the health of the nation's children and youths at an estimated cost of $6 billion to $10 billion a year.

The commission recently disclosed its recommendations to the annual meeting of the American Psychiatric Association in advance of its report to Congress. The 54-member commission—which has completed a three-year, $1.5 million study—was established by Congress in 1965.

Sen. Abraham A. Ribicoff (D., Conn.), who introduced the legislation to set up the committee, said he would promptly introduce legislation to carry out the commission's recommendations.

The recommendations included national health insurance for persons up to 21- or 25-years-old; family planning and birth control; prenatal care; pediatric care for children up to age three, and physical and mental health services for older children.

Other recommendations included: ● Federal funding for about 100 child-development councils to help guide families through the confusion of Government agencies in order to insure diagnostic, treatment, and preventive services for children ● Appointment of a Presidential council of advisers on children and youth, similar in position and prestige to the Council of Economic Advisers ● Establishment of state commissions and local authorities on child care ● Federal financing of about 10 evaluation centers to consider the working of the child development councils ● Publicly-supported day care available for all children ● Federal funds for training child health and weifare personnel ● Tax incentives to induce people to serve in slum areas.

Reginald S. Louri, MD, a Washington, D.C., psychiatrist, is chairman of the joint commission.

President Nixon, in a Feb. 19 message to Congress said:

"So crucial is the matter of early growth that we must make a national commitment to providing all American children an opportunity for healthful and stimulating development covering the first five years of life."

so light-
headed..."

She's confused...and frightened. Yesterday, her complaint was a brief spell of dizziness. Next week, she may be troubled by prolonged nausea or tinnitus. The symptom of vertigo is a constant problem in geriatrics, and regardless of origin, duration, and frequency, such episodes can result in severe emotional and physical discomfort for the aging patient.

You can help prevent such problems with

BONINE®

(MECLIZINE HCl)

protects most patients against nausea and vertigo up to 24 hours with a single dose.

Whether the symptoms are due to Ménière's syndrome, labyrinthitis, vestibular dysfunction, or cerebral arteriosclerosis, most patients with nausea and vertigo respond remarkably well to Bonine (meclizine HCl). A single dose usually protects up to 24 hours. In difficult cases multiple daily doses may be necessary for maximum response.

One-a-day dosage costs your patients less. And fruit-flavored Bonine chewable tablets are more convenient to take anytime, anywhere—without water. Side effects are infrequent and mild, even with prolonged use.

Precautions: Although the incidence of drowsiness and atropine-like side effects such as dry mouth and blurring of vision is low, the physician should alert the patient to the need for due precautions when engaging in activities where alertness is mandatory. *Use in women of childbearing age:* In weighing potential benefits vs. risk in women of childbearing age, consider the fact that a review of available animal data reveals that meclizine exerts a teratogenic response in the rat. In one study a dose of 50 mg./kg./day (50 times the maximum recommended human dose) produced cleft palate in 2 of 87 fetuses when administered to the rat at critical times during the first 15 days of gestation. At doses of 125 mg./kg./day, meclizine will produce 100% incidence of cleft palate in the rat. At doses of 25 mg./kg./day, decreased calcification of the vertebrae and relative shortening of the limbs were also produced in the rat, but experts disagree as to whether this is a teratogenic response. While available clinical data are inconclusive, scientific experts are of the opinion that this drug may possess a potential for adverse effects on the human fetus. Consequently, consideration should be given to initial use of a nonphenothiazine agent that is not suspected of having a teratogenic potential. In any case, the dosage and duration of treatment should be kept to a minimum.

Supply: 25 mg. scored tablets.

More detailed professional information available on request.

Pfizer LABORATORIES DIVISION
New York, N.Y. 10017

For the "Cheater Eater"

Formulas: Each 'Dexamyl' *Spansule* capsule No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid (Warning, may be habit forming). Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital (Warning, may be habit forming).
Before prescribing, see complete prescribing information in SK&F literature or *PDR*.
Contraindications: Hyperexcitability, undue restlessness, hyperthyroidism, porphyria; in patients on MAO inhibitors.
Precautions: Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Excessive use of the amphetamines by unstable individuals may result in a psychological dependence. Rarely, symptoms of toxic psychosis (hallucinations, confusion, panic states, etc.) may occur with amphetamines, usually after prolonged high dosage. In these instances, withdraw the medication. Use cautiously in pregnant patients, especially in the first trimester.
Adverse Reactions: Overstimulation, restlessness, insomnia, g.i. disturbances, diarrhea, palpitation, tachycardia, elevated blood pressure, tremor, sweating, impotence and headache.
Supplied: In bottles of 50.

Dexamyl®
brand of dextroamphetamine sulfate and amobarbital
Spansule®
brand of sustained release capsules

The Cardiac Patient and Driving

ROBERT J. WILDER, MD
Assistant Professor of Surgery
The Johns Hopkins University
Attending Surgeon
Sinai Hospital
President, Metropolitan Division
Maryland Heart Association

For the welfare of their patients and for all citizens, the physician must judge the ability of an individual to drive safely. There are few guidelines at the present time, but more and more scientific research is being conducted. The 1968 report from the California State Department of Public Health [1] reveals that 15% of drivers dying within 15 minutes of their single vehicle accident died of natural causes, but most important is that 94% of these were due to heart disease. Coronary artery disease was the major culprit and this information points up the need for driving restrictions on patients with heart disease.

From the standpoint of public safety, heart disease is a tremendous problem: over 5,000,000 people die every year in this country from coronary artery disease, and many hundreds of thousands from other forms of arteriosclerotic disease that cause sudden death or loss of consciousness. It has been estimated that 7.8% of the deaths from coronary disease are sudden and unexpected.[2] If we use this figure, approximately 40,000 sudden deaths occur annually in the U.S. from coronary artery disease. How many of these individuals are driving? In addition, not only are automobiles involved, but all motor vehicles—trains, boats and planes, private and commercial.

What can be done to help solve this problem of traffic safety and the cardiac patient? First, an accurate picture must be recorded of the number of drivers who die of natural causes at the wheel. If adequate post-mortem examinations are carried out for all drivers who die in accidents, such information might become available. The number who die of natural causes should be recorded and this information should be brought to the attention of the public, the medical profession and the driver licensing agencies. Legislation and regulation would then be more readily acceptable.

Secondly, physicians must accept the responsibility of advising their patients, who are drivers and have heart disease, about their fitness to drive. It is a well-known fact that persons who have had one coronary heart attack are more likely to have a second episode. Persons unfit to drive must be reported, and physicians must be more realistic with their advice.

Thirdly, legal requirements must be passed that require physicians to report to the state licensing agencies any patient who develops a medical condition which makes him a driving risk. Application blanks, both for initial licensing as well as for renewal, must ask the applicant if he has or has had heart disease.

The State of Washington refuses to issue drivers licenses to persons with heart disease when the condi-

tion has not been controlled for at least three months.[3] A special medical examination is required for any person with bradycardia or tachycardia. All other people with heart disease must submit to a regular physical examination. Deterioration, or an uncontrolled condition, usually results in a suspension of the drivers license. Such restrictions certainly are important if we are going to decrease the number of deaths by natural causes at the wheel.

In 1959, the Committee on Medical Aspects of Automobile Injuries and Deaths of the American Medical Association outlined physical standards for driver licensing, and for guidance of licensing authorities and physicians.[4] Their suggestions are briefly listed below:

1. Rheumatic fever. Any evidence of active rheumatic fever calls for marked restriction of activity, and such a patient should be advised not to drive.

2. Valvular disease. Appraisal must be made of the extent of the damage, the derangement of the rhythm, the progressive cardiac enlargement and the myocardial insufficiency. Obviously, significant aortic stenosis is prone to lead to sudden death and these patients should be advised not to operate a motor vehicle. Uncontrolled disease or deterioration is a definite indication for complete driving restriction.

3. Myocardial insufficiency. For whatever the reason, uncontrolled myocardial failure is an indication for the patient not to drive. A patient, with well controlled myocardial failure, however, may operate a private motor vehicle, but should not operate a commercial or passenger transport vehicle.

4. Disturbance of rhythm. Abnormal rhythm is a frequent complication of heart disease and these individuals may also drive private vehicles when well controlled, but should not be allowed to operate commercial or passenger vehicles.

5. Hypertensive heart disease. Hypertension itself is not disabling for the operation of a motor vehicle but the complications may well be. Therefore, restrictions are placed on the patient when congestive heart failure, angina pectoris or vision changes are discovered.

In general then, limitations are placed on those who have cardiac conditions which are uncontrolled or which may result in sudden death. Although rules, regulations, and restrictions must be made and enforced, at the present time, the physician still plays the major role in advising his patients about their fitness to drive, and in supporting legislation to make reportable, to the Department of Motor Vehicles, all persons unfit to have a license.

Report on Joint Meeting of the State Medical Society Representatives, State Hospital Association Representatives and the Standards Committee of the Joint Commission on Accreditation of Hospitals

The Joint Commission on the Accreditation of Hospitals was established in 1918 for the purpose of setting up standards which hospitals would have to meet in order to become accredited institutions. Since 1918, these standards have remained unchanged. A provisional draft of a revised list of standards was presented to the AMA House of Delegates in June, 1968, which, in turn, passed a resolution requesting that the draft be reviewed by state medical societies and state hospital associations before a final draft was drawn up and enacted.

On February 10, 11, and March 20, 21, 1969, representatives from the state medical societies and hospital associations met with the Standards Committee of the Joint Commission to review the provisional draft and make recommendations. Representatives from the Medical and Chirurgical Faculty were Richard D. Bauer, MD, and Manning W. Alden, MD. Their report is as follows:

Richard Palmer, MD, chairman of the Standards Committee, conducted the meetings and stated at the outset that any recommendations made by the representatives would be reviewed by the Joint Commission, but that the decision as to which recommendations would be incorporated in the final draft would be the sole responsibility of the Commission.

Dr. Palmer explained that the final draft would be presented in two books. Book 1 will contain information regarding accreditation of the hospital itself, ie, requirements as to dietetic services, emergency services, governing body and management, medical staff, medical records, etc. Book 2 will be a more detailed volume dealing with professional aspects of the various divisions of the modern hospital. Book 2, at this time, is in the process of being outlined. This also will be presented for review by hospital and medical society representatives.

Approximately 160 people attended the meetings which were in the form of informal discussions. The sections of the draft covered included dietetic services, emergency services, governing body and management, library services, medical records department, medical staff, nursing staff, pathology, pharmacy, physical therapy services, radiology, and safety.

One of the main points discussed was the establishment of multidisciplinary committees. The provisional draft calls for these committees to be designated by the governing body. Physician representatives at the meeting emphatically stated that this should be under the province of the medical staff, particularly in regard to medically oriented committees having to do with records, utilization, pharmacy and therapeutic analysis, infection control, tissue committee, etc. (All physicians were requested to discuss this with their AMA delegates.)

Another controversial item centered on physician representation on hospital boards of governors. Some hospitals ban physicians from serving in this capacity, and the Standard Committee feels physicians should participate on such boards. Certain members of the Hospital Association argued that no physician should serve in this capacity. They also stated that the president of the staff should not even sit at board meetings in an *ex officio* capacity, with or without a vote. In all fairness, it must be said that some Association members didn't go this far, but in general, the two groups were at odds. The physicians felt that there should be no prohibition of this function and privilege.

In essence, your representatives' opinion was that, since the physician is the *most important single working entity in any hospital,* since hospitals have functioned in the course of history without governing boards, without lay administration, without gas or electricity, sometimes without even nurses, *but never without doctors,* it should be mandatory that physicians be adequately represented on governing boards—not *ex officio*—but right in the middle of that board, with a vote. It was pointed out that less stress should be put on specified meetings of the sterile organization called a Joint Conference Committee, which in many instances exists as a "sop" to the doctors and which would be far less necessary if physicians sat on the board in the first place, making the Joint Conference Committee a sort of *ad hoc* organization which would only meet for specific purposes when needed. This, in turn would cut down on the volume of meetings one had to attend.

The section on nursing seemed to most of us to

concentrate on the administrative aspects of nursing care and we asked that it be rewritten to give the impression, at least, that the nurse's prime duty was patient care, and the paper-work aspect, though necessary, should be secondary.

In regard to the section on Pathology, Dr. Alden asked that the Chief Principle be changed to read: "The hospital shall *assure the availability* of pathological facilities and services adequate to meet the needs of the patient." He would like the Faculty to send in a written request that this be changed.

It was pointed out that hospital laboratories are subject to the constant evaluations of the American Board of Clinical Pathologists and the American Association of Blood Banks. Laboratories that are certified by these groups should have no fear of examination by the JCAH. It was felt, also, that clinical departments in general, which were certified for intern and residency training, are likewise a step ahead. This is one of the reasons the format of JCAH evaluations is being changed.

It is of interest to note that the Joint Commission on Accreditation recognizes that the procedure followed in reviewing a hospital for accreditation has had certain deficiencies. It is hoped that these deficiencies will be corrected in the near future. For instance, it is proposed that once the new standards are adopted, the Joint Commission will send as many as three representatives to a single hospital and these representatives may spend from one to three or more days with that institution going over its various divisions in minutia. The time allotted to each institution and the number of persons visiting that institution will, of course, be governed by the complexity and size of the institution. It was also announced that, prior to the time of inspecting the hospital for new accreditation or re-accreditation, the state medical society in that state would be advised far enough in advance so that they could provide the Joint Commission with information on particularly troublesome areas in that hospital.

As referred to above, the greatest amount of discussion of the standards tended to center around the question of (1) due process and (2) the presence of physicians as voting members on the governing board of a hospital. The summation of the discussion on due process, in effect, established that the Joint Commission will require, as a part of the bylaws of a medical staff, the opportunity for a physician to have a hearing in the event privileges to practice in a given institution are denied, or in the event privileges previously granted are reduced or removed at any time. Secondly, the Joint Commission will probably include in the new regulations a requirement that there be no restriction to physician staff members serving as voting members of a hospital board.

PAUL F. GUERIN, MD, CHAIRMAN
Library and History Committee
ELIZABETH SANFORD
Librarian

library

What Kinds of Questions is a Medical Reference Library Asked?

Questions coming into our library are varied, interesting, technical, and occasionally absurd. However, we make every effort that we, as librarians, not physicians, are capable of, or that we consider to be within our province. Often, a perturbed patient calls the library to find out whether a drug prescribed by his physician may be causing adverse reactions. Others call in hopes of finding a diagnosis of their conditions without the need for consulting a physician.

Diagnosticians librarians are not, so we kindly remind callers that they will need to see their own physician, or that we will assist them in locating a general practitioner, or specialist, as the need demands. Many want a "rating" on physicians and register surprise when the librarian informs them we have no such "rate book". Another type of question comes in this form: "Who is the best ear man, or heart specialist, or hand surgeon?" Aside from these oft-repeated questions, though, others of interest received in the last four months have included:

Who are physicians using hypnotism in psychiatry? Obstetrics? For treatment of obesity?

Hair transplants—is it safe? Who performs transplants in Baltimore?

Can you describe the duties of a medical director in a hospital?

Can you furnish the name of a heart specialist in Taipei?

Can a naturopath practice in Maryland?

Know a German-speaking psychiatrist in Baltimore?

Suggest a physician specializing in Hodgkin's Disease?

Have you pictures of old quarantine signs?

Where can I offer myself for research on the reappearance of mouth ulcers periodically?

What birth control methods are used in foreign countries?

Dates of Dr. Henning Waldenström, Swedish physician? (This was found through the Swedish embassy via cable to Stockholm.)

Name of the organization(s) experimenting with freezing bodies (cryonics)?

Will you refer me to obesity clinics in Baltimore?

American-trained doctors practicing in Munich?

What does 89 mean in diabetes diagnosis?

What substitutions can be made in a baby's diet?

Do you have records showing names of *all* physicians practicing in Maryland since its beginning?

Can you send a sample of an agreement to share offices?

Do you have a book on illnesses of U.S. presidents and information about their physicians?

Please suggest a psychiatrist interested in literature, mainly novels and poetry?

Do you know of a beautiful female psychologist I could consult? I might as well see some beauty if I have to spend my money this way! (No, we couldn't; at least not in Baltimore. If you know one, let the library know please.)

(The above questions were selected from a daily record of telephone requests.)

First Meeting, 171st Annual Session, House of Delegates
(264th Meeting)
Medical and Chirurgical Faculty of the State of Maryland
Wednesday, April 9, 1969
The Alcazar, Baltimore, Maryland

The 264th meeting, first of the 171st Annual Session, of the House of Delegates of the Medical and Chirurgical Faculty of the State of Maryland was called to order at 9:40 a.m., Wednesday, April 9, 1969, at The Alcazar, Baltimore, Maryland, the President and Secretary being present.

The following delegates (or alternates) were registered as being in attendance; an asterisk indicates an alternate delegate.

Robert T. Adkins, Wicomico County
Manning W. Alden, Council
Timothy D. Baker, Baltimore city
John G. Ball, Council
James W. Banks, Washington County
Richard D. Bauer, Past President
Francis J. Borges, Baltimore city
M. McKendree Boyer, Past President
Henry A. Briele, Council
*G. Cader, Baltimore city
Douglas Gordon Carroll, Baltimore city
Katharine A. Chapman, Montgomery County
John T. Chissell, Council
John N. Classen, Baltimore city
Shirley R. Clinton, Baltimore city
Archie R. Cohen, Council
Kenneth Cruze, Montgomery County
William B. Culwell, Carroll County
*Luis M. Cuza, Cecil County
Worth B. Daniels, Jr., Baltimore city
Melvin B. Davis, Baltimore County
John B. De Hoff, Baltimore city
DeWitt E. DeLawter, Montgomery County
John M. Dennis, Council
*Michael Dobridge, Montgomery County
J. Sheldon Eastland, Past President
Wm. Carl Ebeling, Council
Wolcott L. Etienne, Council
James McC. Finney, Harford County
Vincent J. Fiocco, Carroll County
Whitmer B. Firor, Past President
Russell S. Fisher, Council
*Abraham Genecin, Baltimore city
*Robert B. Goldstein, Baltimore city
Edward G. Grau, Baltimore County
Paul F. Guerin, Council
William B. Hagan, Council
Louis E. Harmon, Baltimore city
John Collins Harvey, Council
Wm. G. Helfrich, Baltimore city
Thomas F. Herbert, Howard County
Philip W. Heuman, Harford County
Claude D. Hill, Baltimore city
H. Logan Holtgrewe, Anne Arundel County
J. Parran Jarboe, Council
Page C. Jett, Calvert County
Frederick M. Johnson, Charles County
Ferd E. Kadan, Baltimore city

Charles E. Wright, Frederick County
*N. Louise Young, Baltimore city
Raymond M. Yow, Council

Present also were staff personnel.

INVOCATION

Mr. Arne Larson, Assistant Director, Department of Medicine and Religion, American Medical Association, delivered the invocation.

ANNOUNCEMENTS

The President made certain announcements with regard to the conduct of business at the session.

MINUTES

The minutes of the House of Delegates of September 5 and 6, 1968 semiannual session, having been distributed to the members and having been approved by the Executive Committee, were presented to the House for information.

INTRODUCTION OF GUESTS

The President introduced Richard W. Corbitt, MD, President of the West Virginia State Medical Association, who spoke briefly to the House.

NECROLOGY

After the Secretary read the following names of deceased members, the members of the House of Delegates rose in observance of a moment's silence in respect for their deceased colleagues:

Anne Arundel County

Abramson, David L.	May 25, 1968
Benedict, Ludwig	May 13, 1968
Faubert, Gustav H.	September 10, 1968
Sheehan, Joseph C.	March 23, 1969

Baltimore city

Bawden, George A.	June 20, 1968
Bernstein, Alan	February 24, 1969
Bix, Harold H.	December 23, 1968
Cohn, Clarence L.	May 26, 1968
Cox, William F., III	November 5, 1968
Cross, Ernest S., Sr.	May 5, 1968
Edmonds, Charles W.	November 18, 1968
Fort, Wetherbee	December 27, 1968
Kane, Harry F.	December 5, 1968
Kern, M. Howard, Sr.	October 4, 1968
Kirkman, Walter N.	July 8, 1968
Loker, F. Ford	October 4, 1968
Parsons, John W.	April 20, 1968
Rosenfeld, Morris	February 17, 1968

SPECIAL RECOGNITION OF DECEASED MEMBER

Russell S. Fisher, MD, President-Elect, offered the following resolution in memory of a distinguished member who had died during the previous year, which was adopted unanimously.

WETHERBEE FORT, MD 1895-1968

Whereas, Wetherbee Fort, MD, died on Friday, December 27, 1968; and

Whereas, As the son of a distinguished physician, he was an outstanding example of an individual who expressed compassion, understanding and concern for his patients; and

Whereas, His devotion to the profession and its ideals did not stop there, but carried over into the activities of the Medical and Chirurgical Faculty of the State of Maryland, as well as in the Baltimore City Medical Society; and

Whereas, He served in many offices at a local, state and national level; and

Whereas, His enthusiasm, his energy and his judgment did much to improve the position of the Faculty; and

Whereas, His ability and industry brought financial soundness and integrity to the operations of the Medical and Chirurgical Faculty; and

Whereas, His distinguished record of accomplishments, his rare qualities of mind and heart, his devotion to the profession endeared him to all, be it therefore

Resolved, That this resolution be spread upon the minutes of the Medical and Chirurgical Faculty's House of Delegates session on Wednesday, April 9, 1969; and be it further

Resolved, That a copy of this resolution be sent to the relatives of Wetherbee Fort, MD, with the notation that this recognition of his efforts on behalf of the Faculty are in this small way hereby acknowledged.

RESOLUTION HONORING DEAN WILLIAM S. STONE ON HIS RETIREMENT

Russell S. Fisher, MD, President-Elect, presented the following resolution honoring Dean William S. Stone, MD, of the University of Maryland School of Medicine, on the occasion of his retirement as Dean, which was adopted unanimously:

Whereas, The year 1969 will see the retirement of William S. Stone, MD as Dean, University of Maryland School of Medicine, and

Whereas, Dean Stone served as Director of Medical Education and Research at the University of Maryland School of Medicine from 1950 to 1954, and Dean from 1954 to 1969, and

Whereas, During this period of time he has brought the educational standards of the School of Medicine to its present high state, and

Whereas, Previous to assuming these responsibilities he served with distinction and honor in the United States Armed Forces from 1929 through 1954, a long and distinguished career; and

Whereas, Dean Stone has gained the respect, admiration and regard of all his colleagues, locally, state-wide and at a national level, and

Whereas, During this period of time he has brought pride and distinction to the University of Maryland School of Medicine, and

Whereas, a person having such distinction and being held in such high regard should receive the honors and credits as his just due, and

Whereas, This House of Delegates of the Medical and Chirurgical Faculty of the State of Maryland wishes to recognize the outstanding ability of Dean Stone, be it

Resolved, That this House of Delegates give a standing ovation to William Spencer Stone, MD, in recognition of its respect and regard for him, and be it

Resolved, That a copy of this Resolution be spread upon the minutes of this session of the House of Delegates, and be it

Resolved, That this be prepared as a suitably engraved scroll and presented to him as a tribute on the occasion of his retirement as Dean of the University of Maryland School of Medicine.

AWARD OF VIET NAM PLAQUES

The President awarded plaques for voluntary service in Viet Nam under the AMA's program of Volunteer Physicians For Viet Nam to the following:

Andre Fesus, MD, Baltimore
Thomas H. Powell, MD, Baltimore
Glendon E. Rayson, MD, Baltimore
Donald K. Wallace, MD, Baltimore
Celeste L. Woodward, MD, Baltimore

PRESENTATION OF FIFTY-YEAR PINS

The President awarded Fifty-Year pins to the following members who were present for the meeting:

Baltimore city:	John A. Buchness, MD
	Robert W. Johnson, Jr., MD
	Charles Reifschneider, MD

Other physicians completing fifty years of Faculty membership but who could not be present were:

Baltimore city:	I. B. Bronushas, MD
	Henry F. Buettner, MD
	Milton H. Cumin, MD
	Louis Krause, MD
	Harry L. Rogers, MD
	D. C. Wharton Smith, MD
	W. Houston Toulson, MD
Baltimore County:	Dawson L. Farber, MD
	H. Lawrence Wheeler, MD
Howard County:	B. Bruce Brumbaugh, MD
Montgomery County:	F. J. Broschart, MD
	Gilbert V. Hartley, MD

EMERITUS MEMBERSHIP

On motion of the Chairman of the Council, John F. Schaefer, MD, the following members who had received the recommendation of their respective societies and the Council, were elected to Emeritus Membership in the Faculty:

Baltimore city:	H. F. Bongardt, MD
	S. DeMarco, MD
	Jacob R. Jensen, MD
	Leo Kanner, MD
	C. W. Peake, MD
Carroll County:	Elizabeth Reese Wilkens, MD
Montgomery County:	John N. Andrews, MD
Washington County:	J. Walter Layman, MD
	Lester M. Shaffer, MD

RESOLUTION 6A/68 CONTINUING ITEM ON HOUSE AGENDA

Dr. Schaefer, Council Chairman, reported that discussions were proceeding with representatives of the Governor's office in connection with Resolution 6A/68, which is to be carried as a continuing item on House of Delegates agendas until the problems in connection with the Medicaid program are resolved. No concrete recommendations are made at this time and a further report

will be made at the Semiannual session.

HONORARY MEMBERSHIP

On motion of Dr. Schaefer, the Chairman of the Council, the following member who had received the recommendation of her constituent society and the council was elected by the required ⅔ vote to Honorary Membership in the Faculty:

Talbot County: Jessie Wright, MD

DISBANDMENT OF PL 89-97 LIAISON SUBCOMMITTEE

On behalf of the Council, Dr. Schaefer, Council Chairman, moved "That the PL 89-97 Liaison Subcommittee be disbanded," which was adopted unanimously.

TREASURER'S REPORT

The Treasurer then presented the 1969 budget for the information of the House, this having been adopted by the Council. The Treasurer then presented the following motion which was unanimously adopted by the House:

> That the MEDIC Network be continued and that sufficient funds be appropriated to the extent needed to finance the operations for the coming MEDIC year.

PRESENTATION OF AMERF CHECKS

The President then presented checks representing voluntary contributions made by Maryland physicians to the American Medical Education and Research Foundation. Henry Siedel, MD, accepted the check for $8,737.11 presented to The Johns Hopkins University School of Medicine; and Dean William S. Stone, MD, accepted the check for $13,550.53 on behalf of the University of Maryland School of Medicine. Appreciation and thanks were expressed by the representatives of the recipients.

PRESENTATION OF PLAQUE TO DEAN WILLIAM S. STONE

The President then presented a plaque honoring Dean William S. Stone, on his retirement as Dean of the University of Maryland School of Medicine.

POLICY AND PLANNING COMMITTEE REPORT

Arthur T. Keefe, Jr., MD, Chairman of the Policy and Planning Committee, on behalf of his Committee moved adoption of his Committee recommendations, which, after discussion and amendment were recommitted to the Policy Planning Committee, together with a pending amendment, for clarification, by a division vote of 43 in the affirmative and 31 in the negative. The recommendations and the pending amendment read as follows:

1. The function of utilization review in Extended Care Facilities should be administered on the local county or regional (group of adjacent counties) level. The Medical and Chirurgical Faculty's role should be one of information and guidance.
2. A committee of the Faculty (already existing or newly appointed if necessary) should be charged with gathering information concerning utilization review from all available sources and stimulating formation of local or regional review committees. This information, along with administrative suggestions should be available to any component societies requesting such.
3. That the Medical and Chirurgical Faculty endorse, as Faculty policy, the principal of utilization review in all Nursing Home Facilities in addition to that required under State and Federal regulations as a means of assuring quality medical care for the patients in such nursing homes.

For the purpose of this recommendation, it is the intention of the Medical and Chirurgical Faculty to be primarily concerned in upgrading the quality of medical care in these facilities.

(Pending amendment underlined)

Definitions of the three types of nursing homes are as follows:

Nursing Home—Extended Care means any institution which renders skilled nursing care to persons suffering from disease or other disabilities. (Skilled nursing care includes care rendered by registered professional nurse or licensed practical nurse under the supervision of a registered nurse.)

Nursing Home—Long Term Care means rendering nursing care (by or under supervision of an RN or a LPN to persons suffering from disease or other disabilities.)

Personal Care Home means any institution which renders personal care (services which an individual would normally perform for himself but for which he is personally dependent on others because of advanced age, infirmity, physical or mental limitations).

BYLAWS COMMITTEE REPORT

Charles F. O'Donnell, MD, Chairman of the Bylaws Committee, on its behalf, moved the adoption of the following bylaw amendments which, after debate, were adopted in each case by more than the required two-thirds vote.

Amend Article XI, by inserting new section 13 to read as follows:

> Section 13. A Committee on Medicine and Religion shall be appointed by the President to consist of not less than six members. It shall be charged with maintaining liaison and effective lines of communication between physicians and clergymen leading to the most effective care and treatment of the patient and his family. It shall also endeavor to assist medical schools and nursing schools in their educational endeavors, and shall be available to theological seminaries for similar assistance—all within the areas of medicine and religion combined.

Amend Article VII, Section 2, by striking out the following:

"authorize physicians' defense"

Amend Article XII, Section 1, by striking out:

"to the Council"

Amend Article XII, Section 2, by striking out:

"On a majority vote, the Council may authorize physicians' defense and the matter"

and inserting:

"Physicians' Defense Cases"

Amend Article II, Section 5, by adding the following new sentence:

"Forty-Year Members who have this status prior to removing from the State of Maryland may continue to hold this type of membership after their removal."

Charles F. O'Donnell, MD, Chairman of the Bylaws Committee, on its behalf, moved the adoption of the following Bylaw amendment which, after debate and a proposed amendment, was recommitted to the Bylaws Committee together with a pending amendment for further study and report.

Substitute for Article IV, Section 3, the following new section which reads as follows:

Section 3. One third of the COUNCILORS provided below shall be elected annually by the House of Delegates from among the active members of component societies comprising the following districts:

(a) Western District: Allegany, Garrett, Carroll, Frederick, and Washington counties

(b) Eastern District: Caroline, Cecil, Dorchester, Kent, Queen Anne's, Somerset, Talbot, Wicomico, and Worcester counties

(c) Central District: Baltimore city, Baltimore and Harford counties

(d) Southern District: Anne Arundel, Calvert, Charles, Howard, and St. Mary's counties

(e) South Central District: Montgomery and Prince George's counties

Representation shall be on the basis of one Councilor from each district, plus one additional councilor for each 200 active and 40-year members in good standing on December 31 each year.

The pending amendment read as follows:

Amend the proposed substitute for Article IV, Section 3, by adding to the final paragraph:

A component society in the central and south-central districts shall be entitled to be represented on the Council as nearly as may be possible by one councilor for each 200 active and 40-year members in good standing of such component society on December 31 of each year.

NOMINATING COMMITTEE REPORT

Richard D. Bauer, MD, Nominating Committee Chairman, presented the following slate:

President-elect (President-elect 1969-70)
Henry A. Briele, Salisbury (President 1970-71)

First Vice-President
John F. Schaefer, Baltimore

Second Vice-President
Charles H. Ligon, Sandy Spring

Third Vice-President
Daniel I. Welliver, Westminster

Secretary
William A. Pillsbury, Timonium

Treasurer
Karl F. Mech, Baltimore

Councilors
Robert B. Goldstein, Baltimore, Central District (1973)
Henry P. Laughlin, Bethesda, South Central (1973)
D. Frank Kaltreider, Baltimore, Central (1973)
John C. Harvey, Baltimore, Central (1973)
Arthur T. Keefe, Jr., Chestertown, Eastern (1973)
William G. Speed, III, Baltimore, Central (1973)
Philip F. Wagley, Baltimore, Central (1973)

Delegate to American Medical Association
Russell S. Fisher, Baltimore
(Jan. 1, 1970—Dec. 31, 1972)

Alternate Delegate to American Medical Association
M. McKendree Boyer, Damascus
(Jan. 1, 1970—Dec. 31, 1972)

Committee on Program and Arrangements:
Julius R. Krevans, Baltimore (1974)

Library and History Committee
Paul F. Guerin, Baltimore (1975)

Finney Fund Committee
Thomas G. Edison, Silver Spring (1975)

Board of Medical Examiners
J. Roy Guyther, Mechanicsville (June 1969—June 1971)
John E. Adams, Towson (June 1969—June 1973)
DeWitt E. DeLawter, Bethesda (June 1969—June 1973)

The floor was opened to further nominations for these offices and there being none, nominations were closed by general consent, the election to be held at the second meeting of the session, Friday, April 11, 1969, at the Faculty building. The nominees for the Board of Medical Examiners are to be elected at the General Session, Thursday, 12:00 Noon, April 10, 1969, at The Alcazar.

INFORMATION COMMITTEE REPORTS

The following reports were distributed in writing for the information of the meeting and an opportunity was afforded at this time to raise any questions:

Report of the Delegates to the American Medical Association—Robert vL. Campbell, MD, J. Sheldon Eastland, MD, Russell S. Fisher, MD, December 1968, Clinical Meeting

Secretary—William A. Pillsbury, MD

Executive Secretary—Mr. John Sargeant

Library and History Committee and Finney Fund Committee—Paul F. Guerin, MD, and D. C. W. Finney, MD

Curator—Edwin David Weinberg, MD

Medical Annals—Leslie E. Daugherty, MD

Committee on Program and Arrangements—Joseph D. B. King, MD

Committee on Contractual Arrangements—J. Howard Franz, MD

Editorial Board, Maryland State Medical Journal—C. Thomas Flotte, MD, Editor

Committee on Emotional Health—Thurman Mott, MD

Finance Committee—Karl F. Mech, MD

Maryland Medical Service, Board of Trustees— J. Sheldon Eastland, MD, President

Med-Chi Insurance Trust—Paul F. Guerin, MD

Medical Emergency Disaster Service Committee—John W. Ashworth, MD

Committee on Postgraduate Education, Preventive Medicine and Public Health—John Whitridge, MD
Membership Committee—William G. Helfrich, MD
Public Relations Committee—Richard A. Young, MD

NOTE: Reports of the following Committees will be presented to the Semiannual Meeting for information and action at that time:

(a) Board of Medical Examiners
(b) Medical Economics Committee
(c) Legislative Committee
(d) Liaison Committee
(e) Mediation Committee
(f) Medicolegal Committee
(g) Occupational Health Committee
(h) Professional Medical Services Committee
(i) Representatives on the Medical Advisory Committee of the Red Cross Blood Bank Program
(j) Auditor's statement for 1968

ANNOUNCEMENTS

The President made certain announcements concerning meetings scheduled during the annual session.

The meeting was adjourned at 11:05 A.M., until 2:00 P.M. Friday, April 11, 1969, at the Faculty Building.

WILLIAM A. PILLSBURY, MD, *Secretary*

Election of the Board of Medical Examiners

A general meeting of the Medical and Chirurgical Faculty of the State of Maryland was held on Thursday, April 10, 1969, at 12 Noon, at the Alcazar, Cathedral and Madison Streets, Baltimore, Maryland, 21201, for the purpose of electing members of the Board of Medical Examiners as follows:

one, for a two-year term
two, for a four-year term

The President, Arthur G. Siwinski, MD, presided and called the meeting to order at 12:14 P.M.

The names of the nominees for the posts shown were presented to the General Meeting as follows:

J. Roy Guyther, MD, Mechanicsville—for two-year term commencing June 1, 1969

John E. Adams, MD, Towson
DeWitt E. DeLawter, MD, Bethesda } —for 4-year term commencing June 1, 1969

Nominations from the floor were requested. There being none, the President declared nominations closed.

Election took place by acclamation and the Secretary, William A. Pillsbury, MD, was instructed to cast one ballot for those nominated.

There being no further business, the meeting adjourned at 12:16 P.M.

WILLIAM A. PILLSBURY, M.D., *Secretary*

Second Meeting, 171st Annual Session, House of Delegates
(265th Meeting)
Medical and Chirurgical Faculty of the State of Maryland
Friday, April 11, 1969
Faculty Building, Baltimore, Maryland

The 265th meeting, second of the 171st Annual Session, of the House of Delegates of the Medical and Chirurgical Faculty of the State of Maryland was held at the Faculty Building, 1211 Cathedral St., Baltimore, Maryland, at 2:00 p.m. on Friday, April 11, 1969, the President and Secretary being present.

The following delegates (or alternates) were registered as being in attendance; an asterisk indicates an alternate delegate:

Robert T. Adkins, Wicomico County
Manning W. Alden, Council
Timothy D. Baker, Baltimore city
John G. Ball, Council
Richard D. Bauer, Past President
*Norman K. Bohrer, Prince Georges County
Francis J. Borges, Baltimore city
M. McKendree Boyer, Past President
Henry A. Briele, Council
*G. Cader, Baltimore city
Robert vL. Campbell, Past President
Douglas Gordon Carroll, Baltimore city
Katherine A. Chapman, Montgomery County
John T. Chissell, Council
John N. Classen, Baltimore city
Archie R. Cohen, Council
Kenneth Cruze, Montgomery County
William B. Culwell, Carroll County
Worth B. Daniels, Jr., Baltimore city
Melvin B. Davis, Baltimore County
John B. De Hoff, Baltimore city
*D. H. Dembo, Baltimore city
DeWitt E. DeLawter, Montgomery County
John M. Dennis, Council
J. Sheldon Eastland, Past President
James McC. Finney, Harford County
Vincent J. Fiocco, Carroll County
Whitmer B. Firor, Past President
Russell S. Fisher, Council
*Abraham Genecin, Baltimore city
*William E. Gilmore, Baltimore city
Gina M. Glick, Allegany County
Marvin Goldstein, Baltimore city
*Robert B. Goldstein, Baltimore city
Paul F. Guerin, Council
William B. Hagan, Council
John Collins Harvey, Council
Wm. G. Helfrich, Baltimore city

Thomas F. Herbert, Howard County
William A. Holbrook, Jr., Prince Georges County
J. Parran Jarboe, Council
Ferd E. Kadan, Baltimore city
James R. Karns, Baltimore city
Arthur T. Keefe, Jr., Council
Robert C. Kimberly, Council
Seruch T. Kimble, Council
Edward L. J. Krieg, Baltimore County
Herbert H. Leighton, Garrett County
*L. Levitsky, Prince Georges County
Charles H. Ligon, Montgomery County
Elmer G. Linhardt, St.Bd. of Med.Exam.
William E. McGrath, Baltimore County
Clarence E. McWilliams, Baltimore County

Thomas E. Van Metre, Jr., Baltimore city
*S. J. Venable, Jr., Baltimore County
Emerson C. Walden, Baltimore city
Wm. C. Weintraub, Prince Georges County
Lawrence R. Wharton, Jr., Baltimore city
Chas. H. Williams, Baltimore County
John G. Wiswell, Baltimore city
Charles E. Wright, Frederick County
*N. Louise Young, Baltimore city
Raymond M. Yow, Council

Present also for the meeting were staff personnel.

INVOCATION

Donald W. Mintzer, MD, gave the invocation.

ELECTION OF OFFICERS

There being no candidates from the floor and there being only one candidate for each of the positions to be filled, by unanimous consent the ballot was dispensed with. The following were then elected by voice vote:

President-elect (President-elect 1969-70)
Henry A. Briele, Salisbury (President 1970-71)
First Vice-President
John F. Schaefer, Baltimore
Second Vice-President
Charles H. Ligon, Sandy Spring
Third Vice-President
Daniel I. Welliver, Westminster
Secretary
William A. Pillsbury, Timonium
Treasurer
Karl F. Mech, Baltimore
Councilors
Robert B. Goldstein, Baltimore, Central District (1973)
Henry P. Laughlin, Bethesda, South Central (1973)
D. Frank Kaltreider, Baltimore, Central (1973)
John C. Harvey, Baltimore, Central (1973)
Arthur T. Keefe, Jr., Chestertown, Eastern (1973)
William G. Speed, III, Baltimore, Central (1973)
Philip F. Wagley, Baltimore, Central (1973)
Delegate to American Medical Association
Russell S. Fisher, Baltimore
(Jan. 1, 1970—Dec. 31, 1972)
Alternate Delegate to American Medical Association
M. McKendree Boyer, Damascus
(Jan. 1, 1970—Dec. 31, 1972)
Committee on Program and Arrangements:
Julius R. Krevans, Baltimore (1974)
Library and History Committee
Paul F. Guerin, Baltimore (1975)
Finney Fund Committee
Thomas G. Edison, Silver Spring (1975)

BOARD OF MEDICAL EXAMINERS ELECTION

The President advised the House that members of the Board of Medical Examiners had been elected in a General Session held on Thursday, April 10, 1969, as follows:

J. Roy Guyther, MD, Mechanicsville, 1969-71
John E. Adams, MD, Towson, 1969-73
DeWitt E. DeLawter, MD, Bethesda, 1969-73

PRESENTATION OF SCROLL TO J.G.F. SMITH, MD

Russell S. Fisher, MD, President-elect, presented a scroll to J. G. F. Smith, MD, of Brunswick, Md., honoring him for 53 years of service to the community.

INTRODUCTION OF GUESTS

The President introduced the following guests of the Faculty, both of whom spoke briefly on behalf of the medical societies they represented:

John F. Kustrup, MD, President, Medical Society of New Jersey
G. E. Farrar, MD, President, Pennsylvania Medical Society

PRESIDENT OF WOMAN'S AUXILIARY

Mrs. H. Leonard Warres, President of the Woman's Auxiliary to the Medical and Chirurgical Faculty of the State of Maryland, requested

permission of the House to speak before it. There being no objection, permission was granted.
Mrs. Warres then read a report of the Auxiliary activities during the past year.

STUDENT AMA PRESIDENT

Mr. David Tapper, President, University of Maryland Chapter, Student American Medical Association, was granted the privilege of speaking to the House by unanimous consent. He reported on the activities of the Chapter during the past year.

MMPAC CHAIRMAN

George G. Finney, Jr., MD, Chairman, Maryland Medical Political Action Committee, spoke to the House, after being granted this privilege. He outlined the activity of the MMPAC Committee during the past year.

REFERENCE COMMITTEE REPORT

Herbert H. Leighton, MD, on behalf of the Reference Committee, presented its report and on behalf of the Committee, recommended that Resolution 1S/68, as amended, be adopted.

RESOLUTION 1S/68 ADOPTED AS AMENDED

The House adopted Resolution 1S/68, which, as amended, read as follows:

Whereas, The United States Government through its various health programs such as, Medicare (Title 18), the Federal Employees Health Insurance Program, and U. S. Armed Forces Dependents Medical Care Program, as well as many others, is based on the concept of payment to the physician of his Usual and Customary Fees; and

Whereas, The United Steel Workers of America has negotiated contracts with their employers that provide for provision of health insurance making payment to physicians on the basis of their Usual and Customary Fees; and

Whereas, The House of Delegates of the Medical and Chirurgical Faculty of the State of Maryland on September 9, 1966, adopted a resolution in which the "resolved" portion reads as follows:

Resolved, That the House of Delegates of the Medical and Chirurgical Faculty of the State of Maryland go on record as urging its members to submit bills for payment of "usual, customary and reasonable fees" for professional services rendered Workmen's Compensation Cases, as well as other governmental agencies; and

Whereas, The present provisions of the Workmen's Compensation Law, Article 101, Section 37(c) reads as follows:

"All fees and other charges for such treatment and services shall be subject to regulation by the Com-
* mission, and shall be *limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living.*" and

* emphasis ours

Whereas, The Workmen's Compensation Commission has authorized hospitals providing services to persons covered under the Workmen's Compensation Laws of this State to bill at their "posted charges," without having to request a hearing and without obtaining permission for any such increases in charges; and

Whereas, Under present regulations of the Workmen's Compensation Commission the individual physician is forced to request arbitration of fees by the Commission when Insurance Carriers elect not to pay the physician's Usual and Customary fees but abide rigidly to the Fee *Guide* published by the Workmen's Compensation Commission; and

Whereas, Within the Medical and Chirurgical Faculty's organization are reliable mechanisms through which questionable fees charged by physicians may be adjudicated; and

Whereas, At least ten other States already work under the concept of Usual, Customary and Reasonable fees for physicians' services in their handling of Workmen's Compensation cases; and

Whereas, There is no reason for medical services rendered to Workmen's Compensation recipients to be compensated for at fees differing from those received for such services rendered to other patients, now therefore, be it

Resolved, That Physicians in Maryland be urged to advise all insurance carriers that they intend to charge their Usual, Customary and Reasonable fees for Workmen's Compensation cases seen by them; and be it further

Resolved, That Insurance Carriers who continue to arbitrarily reduce fees paid to physicians for such Workmen's Compensation cases be taken to court so that a test case can be made to determine if they are in violation of the law as it is presently written; and be it further

Resolved, That physicians who elect not to see such Workmen's Compensation Cases because of this arbitrary attitude on the part of the groups involved so notify the Insurance Carriers, requesting them to seek the services of other physicians for care of such patients.

RESOLUTION 1A/69 ADOPTED AS AMENDED

Dr. Leighton, on behalf of the Reference Committee, moved adoption of Resolution 1A/69, as amended. The House adopted Resolution 1A/69, as amended, which read as follows:

Whereas, We as physicians have noted a tremendous increase in the number and type of the various group health insurance programs; and

Whereas, We believe these programs if properly handled can be of great benefit to both employers and employees as well as the general public, and

Whereas, There is a current tendency on the part of some insurance companies to reduce policy benefits in order to sell substandard policies at lower prices to employers who are not aware of the facts and who lack

the requisite expertise to compare and evaluate competing plans; and

Whereas, Physicians through their national, state and county medical societies are in a unique position to advise and counsel with employers, employees, insurance companies and the general public in health insurance matters; now, therefore, be it

Resolved, That the Medical and Chirurgical Faculty of the State of Maryland establish a committee whose purpose it shall be to formulate model group hospital and medical insurance master policies for use by employees, employers, insurance companies and members of the general public in this State; and be it further

Resolved, That said committee shall thereafter furnish consultation services to interested persons, firms or groups with respect to such insurance programs so that each party to such transactions can be made fully aware of the essential elements of proposed insurance plans in order that they may intelligently evaluate and compare the same.

RESOLUTION 2A/69 REJECTED

Dr. Leighton on behalf of the Reference Committee, moved that Resolution 2A/69 *NOT* be adopted. The House, after debate, rejected Resolution 2A/69, which read as follows:

Whereas, The Joint Commission on Accreditation of Hospitals specified that:

". . . the Joint Commission on Accreditation of Hospitals reaffirms its conviction that history-taking and physical examination of a patient admitted to a hospital is a part of the practice of medicine; their unsupervised performance and unreviewed recording by medical students are not conducive to the best quality of medical care, are not a useful learning experience, and may place the extern, the attending physician and the hospital in legal jeopardy. They cannot therefore be considered acceptable practices in an accredited hospital, as either an economic resource for students or a time-saving device for physicians."

and,

Whereas, It is obvious from such a statement that any patient who is scheduled for surgical procedures or who is in need of a medical regime that requires the skills of a licensed physician should have such history and physical examination authenticated by the attending physician or a qualified individual (by that is meant a licensed physician); and,

Whereas, It has become known that this is not always the practice that is being followed in some hospitals that utilize the services of externs; and

Whereas, Such practices cannot be condoned under any circumstances; be it, therefore,

Resolved, That the Medical and Chirurgical Faculty of the State of Maryland, in the interest of better patient care, requires that BEFORE SURGICAL PROCEDURES ARE PERFORMED AND BEFORE MEDICAL REGIMES OR TREATMENT ARE ESTABLISHED, that histories and physicals performed by externs or house staff, be properly authenticated and approved by a legally licensed physician.

RESOLUTION 3A/69 REJECTED

Dr. Leighton, on behalf of the Reference committee, moved that Resolution 3A/69 *NOT* be adopted. The House rejected Resolution 3A/69, which read as follows:

Whereas, The American Medical Association has sent guidelines to the Medical and Chirurgical Faculty dealing with telephone listings of physicians; which included a statement that control should be at the local society level; and

Whereas, The Medical and Chirurgical Faculty Council (11-11-67) has taken action to enforce its own interpretations of these guidelines without placing control at the local society level; and

Whereas, The enforced terminology "practice limited to" without further explanation has been misinterpreted by patients, in some localities, that certain doctors no longer practice subspecialties; therefore, be it

Resolved, That telephone listings should be made in accordance with guidelines established by the local component societies which will consider, but not necessarily rigidly adhere to the guidelines established by the American Medical Association as interpreted by the Council of the Medical and Chirurgical Faculty; and be it further

Resolved, That a copy of this resolution be forwarded to the C & P Telephone Company and to the Reuben H. Donnelly Telephone Directory Company.

RECORDING OF VOTE

The Washington County delegation was granted permission to have it recorded in the minutes that the delegation had voted to support the resolution as introduced; and as it was instructed to do by its component society.

RESOLUTION ON APPOINTMENT OF SECRETARY OF HEALTH AND MENTAL HYGIENE

Timothy Baker, MD, requested consideration by the House of a motion dealing with the appointment of a Secretary of Health and Mental Hygiene by the Governor. By more than a two-third vote, the House voted to consider this motion. The motion, then adopted by the House by unanimous vote, read as follows:

That, the Medical and Chirurgical Faculty of Maryland goes on record as offering the Governor any advice, information, or consultation that he should wish in connection with the important task of appointing a Secretary of Health and Mental Hygiene.

BYLAW AMENDMENT PROPOSAL REJECTED

Raymond C. V. Robinson, MD, on behalf of the Baltimore City Delegation, offered the following motion to the House which, after debate and a division vote was rejected by 20 in the affirmative and 60 in the negative.

On behalf of the Baltimore City Medical Society delegation, I move that the Bylaws Committee be directed to prepare a bylaw amendment for presentation to the semiannual meeting in September 1969, whereby those component societies which are guaranteed representation on the Council by the bylaws, may elect those Councilors it wishes to have represent it.

NEW PRESIDENT

The Chair then introduced Russell S. Fisher, MD, new Faculty President, who assumed the chair.

ANNOUNCEMENTS

The Chair then made certain announcements.

ADJOURNMENT

The President, by general consent, declared the House adjourned *sine die*, at 3:25 P.M.

Franklin Square Hospital Nearing Completion

The new $7,000,000 Franklin Square Hospital on Ridge Road, in eastern Baltimore County, is taking its final shape and will be ready for occupation late this year.

Widely heralded as an advanced concept in hospital design, the modern facility will house its patients in a four-story wing which extends 330 feet along one elevation. Adjoining is the two-story core of the hospital where diagnostic and treatment activities will be centered. The building is reinforced concrete with a brick facing. Tinted glass will be used to reduce the glare in the aluminum window frames. Floor space is the equivalent of about four acres.

Facilities in the hospital will include seven operating rooms, an X-ray department, and pathology laboratory, as well as thoroughly up-to-date emergency equipment.

Patient rooms will be equipped with toilets. Lavatories will be adjacent to each bed. Each room has been designed with a comfortable alcove in which the patient can relax and enjoy the attractive landscaping around the hospital.

In addition to the usual closets for clothing and personal effects, the rooms will have "pass through" cupboards in which patient supplies are placed from the corridor and removed through doors inside the room.

The modern lighting system will combine general illumination with reading light. Two-way patient-nurse communication is being installed; and switches, television controls, and nurse calls will be placed to insure the utmost in patient convenience.

The new Franklin Square Hospital will be the first in this area to use the "convenience" food system. Food will be supplied by major processors in the form of frozen, prepared meals. This system will permit the hospital to offer a more uniform quality and greater variety of food at a lower cost.

The hospital is an important unit in the health-education complex that includes Essex Community College and a county health center. Franklin Square is now engaged in raising funds to purchase all new equipment and furnishings for the building; and to expand its medical staff to meet the heavier patient load at the new site.

The Franklin Square Foundation, created for "charitable, scientific, and educational purposes", is considering the construction of other buildings to increase the complex and provide space for offices, laboratories, related facilities, and housing for interns and residents.

NEW SURGERY HEAD

Dr. Ferris

Philip J. Ferris, MD, of Washington, D.C., has been named full-time director of the Department of Surgery at Franklin Square Hospital, effective July 1, 1969.

As director, Dr. Ferris will be responsible for the organization of all surgical activities, including sub-specialty appointments, and will direct an American Medical Association - approved four-year program for training new surgeons.

Dr. Ferris was a scholarship student at The Johns Hopkins University, from which he received an AB in 1954. In 1958, he received his MD from The Johns Hopkins University School of Medicine.

* * *

George A. Lentz, Jr., MD, assistant professor of pediatrics, and preventive medicine and rehabilitation, has been appointed assistant dean for student affairs in the University of Maryland School of Medicine.

* * *

Robert Traub, PhD, research professor in the department of microbiology, University of Maryland School of Medicine, returned to Baltimore in December from a three-and-a-half month visit to New Guinea, where he was conducting research on viral and rickettsial infections. On his return, Dr. Traub was invited by the Entomological Society of America to present two papers at its meeting in Dallas, December 2-6.

* * *

On January 9-10, **Erland Nelson, MD,** professor and head of the department of neurology, **Jerome Merlis, MD,** professor of neurology and clinical neurophysiology, **Albert Heck, MD,** associate professor of neurology, and **Thomas Price, MD,** assistant professor of neurology, represented the University of Maryland School of Medicine at the Third Annual Cerebrovascular Clinical Research Center Workshop in San Juan, Puerto Rico.

* * *

Richard D. Richards, MD, professor and head of the department of ophthalmology, and **Drs. Moritz Michaelis** and **Stanley S. Schochet,** both associate professors of ophthalmology, University of Maryland School of Medicine, presented a paper at the annual meeting of the Association for Research in Ophthalmology in Sarasota, Florida, on April 20-24. The Atlantic Section meeting of the association, which was held in Baltimore on March 7-8, was organized by the department of ophthalmology.

* * *

Harlan I. Firminger, MD, professor of pathology, University of Maryland School of Medicine, chaired a session on neoplasia at the American Association of Pathologists and Bacteriologists in San Francisco in March. At the same meeting, **Si Chun Ming, MD,** associate professor, and **Pen Ming Ming, MD,** assistant professor, both in the department of pathology, delivered a paper.

* * *

Roy Hertz, MD, has been awarded the Ann Langer Cancer Research Foundation Award for 1969 for his effective chemotherapy of trophoblastic tumors in women. Dr. Hertz is chief, Reproduction Research Branch, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Md.

The Ann Langer Cancer Research Foundation is a Chicago group with a membership of 150 lay persons who raise funds for cancer research. To date, over $200,000 has been given by this foundation to such groups as, the University of Chicago Cancer Research Foundation, Mount Sinai Hospital, Hebrew University in Jerusalem, and others.

* * *

AMA President-elect, **Gerald D. Dorman, MD,** of New York city, has been named to the HEW Advisory Committee on Health Protection and Disease Prevention. The committee is being asked to make recommendations on the role of the federal government in preventing illness, and in planning a major expansion of the effort to reduce the incidence of disease. A report is due by February 1, 1970.

* * *

A Drug Abuse Clinic that initially can treat 40 to 50 narcotic addicts on an outpatient basis has been formed at The Johns Hopkins Medical Institutions, and is accepting its first patients. **Leon Wurmser, MD,** is the clinic director.

The clinic's programs are being financed by grants from the Federal Department of Health, Education and Welfare, and the State Department of Mental Hygiene. The state already has made the first of six annual $40,300 payments.

* * *

The National Institute of Mental Health has launched an intensive drug abuse information program. A Washington metropolitan area television and radio campaign is the first phase of an all-media national effort.

Nation-wide advertising began in April, dealing with the dangers of LSD, amphetamines, barbiturates, narcotics, and general drug abuse. The commercials also stress the legal penalties for possession and use of marihuana.

Stanley F. Yolles, MD, Director of the Institute, has stated that the advertising will be supplemented by a national grassroots educational program. Films and question-and-answer fliers are already in circulation.

* * *

The Association of American Physicians and Surgeons, Inc., in its April Newsletter that reaches physicians in all 50 states, singled out the members of **The Professional Forum of Baltimore** "for their important assistance to AAPS and to its Committee for the Education of Medical Students, Interns, and Residents."

Selected for this accolade was **Jack Rytten,** a Baltimore criminologist and investigator, who is president of The Professional Forum, and **Henry L. Wollenweber, MD,** who serves as vice-chairman of the Forum's Committee On Medicine. Dr. Wollenweber also serves as liaison coordinator between The Professional Forum and the Association of American Physicians and Surgeons, Inc., a Chicago-based, nation-wide group of physicians.

In a statement to *The Daily Record,* Mr. Rytten said: "The Professional Forum will continue to give its unwavering support to the immediate and long-range goals of the Association of American Physicians and Surgeons, Inc. in that group's efforts to restore the Free-Enterprise Concept to the practice of medicine."

* * *

Robert E. Cooke, MD, pediatrician-in-chief at The Johns Hopkins Hospital, and **Ralph W. Gause, MD,** chairman of the department of obstetrics and gynecology, the Roosevelt Hospital, New York city, have been appointed medical consultants to the National Foundation-March of Dimes. Dr. Cooke will work closely with the Foundation's efforts to improve the care and treatment of children with birth defects, and Dr. Gause will assist in development of expanded programs in prenatal care to prevent birth defects.

* * *

Dr. Cooke was the principal speaker at the April 21 dedication ceremonies for the Center for Developmental and Learning Disorders at the Medical Center of the University of Alabama.

* * *

Octavio deMarchena, MD, has been Board Certified by the American Board of Surgery.

* * *

D. S. Hathaway, MD, who has been a resident in nephrology in the Mayo Graduate School of Medicine, University of Minnesota at Rochester, has left that city and will be located in Bethesda, Maryland.

* * *

Jon Valigorsky, MD, intern in pathology, University of Maryland Hospital, presented a paper at the April meeting of the Federation of Societies for Experimental Biology and Medicine in Atlantic City.

* * *

Governor Marvin Mandel and the members of the Maryland General Assembly have been praised for their action on Maryland's community mental health program by **Reuben Shiling,** President of the Maryland Association for Mental Health (MAMH).

Mr. Shiling lauded Governor Mandel's inclusion of $1.8 million for community mental health services in his Supplementary Budget Request. The General Assembly approved the request in full.

Governor Mandel

* * *

William G. Esmond, MD, assistant professor of surgery, University of Maryland School of Medicine, presented an exhibit and six papers at the 21st Annual Conference on Engineering in Medicine and Biology in Houston, Texas, in November. He has also prepared a scientific display for the April meeting of the American Association for Artificial Internal Organs in Atlantic City.

* * *

The Maryland Association For Mental Health (MAMH) has published a brochure entitled, "Your Mental Health Association in Maryland." The brochure, which is free to the public, outlines the purpose of mental health associations and illustrates some of their activities. Copies may be obtained by contacting the MAMH at 2104 North Charles Street, Baltimore, Maryland 21218.

* * *

The world's most powerful neutron generator designed specifically for cancer research, **the Dynagen IV,** developed and manufactured by Radiation Dynamics, Inc., will be used by the Cleveland Clinic in a research program for tumor therapy.

According to **Antonio Rodriquez-Antunez, MD,** director of the Cleveland Clinic's Radiation Therapy and Nuclear Medicine Department, recent cancer investigations have shown some distinct advantages of fast neutron treatment as compared to conventional super-voltage X-ray and cobalt 60 teletherapy techniques. These investigations have been underway for a number of years at the Hammersmith Hospital, London, England, and have demonstrated limited success for the treatment of large, solid tumors.

* * *

Directors of state comprehensive health planning agencies have organized into the **American Academy of Comprehensive Health Planning** (AACHP). The Academy, whose bylaws were officially approved on March 5, has been formed to promote increased understanding of comprehensive health planning. The new organization will also serve as an information exchange among national, state, and local comprehensive health planning authorities and agencies.

Eugene H. Guthrie, MD, executive director of the Maryland Comprehensive Health Planning Agency, was elected Chairman of the AACHP.

* * *

On May 1st, the **Institute of International Education** officially opened its competition for 275 grants for graduate study or research abroad, and for professional training in the creative

and performing arts during the academic year 1970-1971.

IIE annually conducts the competition for U.S. Government Awards under the Fulbright-Hays Act and the competition for grants offered by various foreign governments, universities, and private donors. The purpose of the grants is to increase mutual understanding between the people of the U. S. and other countries through the exchange of persons, knowledge, and skills.

Candidates who wish to apply for an award other than in medicine must be U. S. citizens at the time of application, have a bachelor's degree or its equivalent before the beginning date of the grant, and, in most cases, be proficient in the language of the host country. Applicants in the field of medicine must have an MD degree at the time of application.

Selections will be made on the basis of academic or professional record or both, the feasibility of the applicant's proposed study plan, language preparation, and personal qualifications. Preference is given to applicants between the ages of 20 and 35 and to candidates who have not had prior opportunity for extended study or residence abroad, with the exception of those who have served in the armed forces.

* * *

In response to a growing program funded by the National Institute of Mental Health, a reorganization and a new post within the NIMH Division of Mental Health Service Programs has been announced by **Alan I. Levenson, MD,** Division Director.

The program—federal aid for the construction and staffing of community mental health centers—will be handled by a new Community Mental Health Centers Support Branch. Previously, two separate branches of the division administered grants to centers.

Appointed to the newly-created Post of Associate Director for Community Mental Health Services is **Saul Feldman, MD.**

* * *

David B. Skinner, MD, assistant professor of surgery, The Johns Hopkins University School of Medicine, has been appointed a Markle Scholar in Academic Medicine by the John and Mary R. Markle Foundation of New York.

The 34-year-old surgeon is one of 25 young medical scientists, all faculty members of medical schools in the U. S. and Canada, selected by the Foundation to receive the $30,000 awards. The money will be paid at the rate of $6,000 per year for five years to the medical schools where the scholars teach and conduct research.

* * *

The outpatient clinic of **Springfield State Hospital** moved from its present location at 2100 Guilford Avenue to its new site at 2646 North Charles Street on April 7.

According to **Frederick Pokrass, MD,** acting hospital superintendent, the new facilities have been made available through the philanthropic generosity of the United Order of True Sisters, Inc. Baltimore #35 which is defraying rental costs.

Evelyn J. Nelson, MD, is clinic director and **Mrs. Robert Taylor** is True Sisters president.

* * *

The newly-created **department of neurology** at The Johns Hopkins University School of Medicine will add five new faculty members to its staff July 1, according to **Guy M. McKhann, MD,** Kennedy Professor and director of the department. The new faculty members are:

Richard C. Johnson, MD, who has been appointed Dwight D. Eisenhower-United Cerebral Palsy Clinical Professor of Neurology. Dr. Johnson is now associate professor of neurology at Case Western Reserve School of Medicine and a neurologist at the Cleveland Metropolitan Hospital.

Daniel B. Drachman, MD, who has been appointed associate professor of neurology, is an assistant professor of neurology at Tufts University.

John M. Freeman, MD, who has been appointed associate professor of neurology, is an assistant professor of pediatrics and medicine (neurology) at Stanford University.

Robert M. Herndon, MD, who has been named associate professor of neurology, is an assistant professor of Medicine (neurology) at Stanford University.

Leslie P. Weiner, MD, who has been appointed assistant professor of neurology, is a special research fellow at The Johns Hopkins School of Hygiene and Public Health.

* * *

Erland Nelson, MD, has just received support in the form of a $10,000 grant from the National Institute of Neurological Diseases and Stroke to test whether reducing moderate hypertension in patients who have suffered one stroke will help them to avoid another one.

Dr. Nelson is head of the department of neurology at the University of Maryland School of Medicine. Collaborating with him in his work are: **Albert F. Heck, MD,** project director; **Thomas R. Price, MD,** and **John W. Eckholdt, MD,** neurologists; **Y. C. Lee, MD,** cardiologist; **William Law, MD,** internist; and nurse **Carol Haina,** project coordinator.

* * *

Vernon E. Krahl, MD, professor of anatomy at the University of Maryland School of Medicine, has found a way to treat a disease, sometimes referred to as

respiratory distress syndrome of the newborn, that tops the list for fatalities among newborn babies. Dr. Krahl prefers to call the disease pulmonary hypoperfusion syndrome (PHS) because his observations have convinced him that the basic trouble is inadequate blood flow in the capillary bed of the lungs.

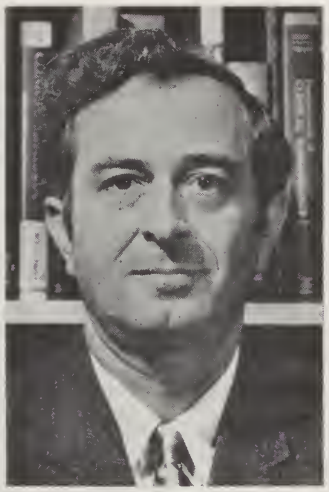
Dr. Krahl has accepted an invitation to spend several months at the Katholiek Universiteit te Leuven in Louvain, Belgium, in collaborative study of PHS with Professor Joseph Lauweryns, head of the school's department of histopathology, and Nadia Bourgeois, MD, pediatrician.

* * *

Howard A. Naquin, MD, has been re-elected as president of the board of directors of the Maryland Society for the Prevention of Blindness. He will serve a one-year term to expire in 1970.

Also re-elected to the board of directors were **Richard E. Hoover, MD, Arnall Paz, MD,** and **Richard D. Richards, MD. Angus L. MacLean, MD,** is among the members of the board.

* * *



Julio E. Alarcon, MD, a resident at University of Maryland Hospital in Baltimore, has placed third in the 1969 SAMA-Eaton Medical Art Award Competition. Dr. Alarcon received $50 and a plaque for his medical illustrations.

* * *

Louis C. Lasagna, MD, director of the Division of Clinical Pharmacology at The Johns Hopkins University School of Medicine, is featured in the cover story of the April 7, 1969 issue of *Modern Medicine.*

Dr. Lasagna, selected by the medical journal's editors as their "Contemporary" for this issue, gives his opinions about care of retarded children (his son is a mongoloid child), doctor use, and patient attitudes toward drugs, including oral contraceptives, and the trend toward active participation by students in shaping educational programs.

For 16 years Dr. Lasagna has served at Johns Hopkins—the past 12 as division director and associate professor of pharmacology and experimental therapeutics. He served earlier, from 1951-1952, as an instructor and, from 1954-1956, as assistant professor of medicine and pharmacology. He also managed to find time to author the book, *Life, Death and the Doctor.*

Dr. Lasagna

* * *

The Suburban Maryland Chapter of the Washington Psychiatric Society has elected the following officers: **Henry P. Laughlin, MD,** chairman; **Brian Crowley, MD,** vice chairman; and **Kenneth Gaarder, MD,** secretary-treasurer.

Membership in the new organization is open to psychiatrists who practice or reside in Montgomery or Prince Georges counties.

* * *

The Air Pollution Control Association is soliciting papers for the **December 1970 Conference of the International Union of Air Pollution Prevention Associations** to be held in Washington, D.C.

Subjects include Medicine and Biology—the effects of air pollution on people, animals, and vegetation; and Air Pollution Surveys—papers reporting community and area studies. **Proposals to present papers may be submitted from July 1969 to January 31, 1970, the deadline.** Papers from the United States of America should be sent to Professor Arthur C. Stern, Program Co-Chairman, Department of Environmental Sciences and Engineering, School of Public Health, University of North Carolina, P. O. Box 630, Chapel Hill, N.C. 27514.

* * *

The formation of a **Mental Health Advisory Committee to the Baltimore City Health Department** has been announced. This group, consisting of leaders in the field of mental health and others whose daily work brings them in close association with the problems of mental health, will serve to coordinate and plan for the improvement and expansion of mental health programs in the Baltimore area.

Members of the committee include: Irvin H. Cohen, MD, director of training at Sheppard & Enoch Pratt Hospital; John H. Hirschfeld, president of the Baltimore Area Council on Alcoholism; Michael J. Bisco, MD, a member of the Maryland Association of Private Practicing Psychiatrists; Addison W. Pope, MD, regional mental health director of the Department of Mental Hygiene; and Paul V. Lemkau, MD, professor, Department of Mental Hygiene, The Johns Hopkins School of Hygiene and Public Health.

The trouble with women...

frequently is men

FLAGYL®
brand of metronidazole

Cures Trichomonal Infection in Both

Although *Trichomonas vaginalis* infection occurs in only 5 to 10 per cent* of men, careful diagnosis will demonstrate the condition in about half of all husbands of infected women. Nine investigators* reported an average incidence of 50.8 per cent in exposed consorts.

Many clinicians have achieved a high degree of success in treating trichomonal vaginitis only after they have recognized the importance of sexual partners in perpetuating the infection. Crowley* has asserted, "it was not until we acted on this key premise that we were able to obtain positive and lasting results in our management of recurrent vaginal trichomoniasis."

Simple ten-day oral treatment with Flagyl virtually assures elimination of established trichomonal infection in men. In twenty-two of twenty-seven studies* data on the results of treating male patients revealed that all men treated with Flagyl were cured.

Indications: Flagyl is indicated in the treatment of trichomoniasis in both men and women.

Contraindications: Pregnancy; disease of the central nervous system; evidence or history of blood dyscrasia.

Precaution: Complete blood cell counts should be made before, during and after therapy, especially if a second course is necessary.

Side Effects: Infrequent and minor side effects include nausea, metallic taste and furry tongue. Gastrointestinal disturbances, flushing and headache sometimes occur, especially with concomitant ingestion of alcohol. The taste of alcoholic beverages may be altered. Other effects, all reported in an incidence of less than 1 per cent, are diarrhea, dizziness, vaginal dryness and burning, dry mouth, rash, urticaria, gastritis, drowsiness, insomnia, pruritus, sore tongue, darkened urine, anorexia, vomiting, epigastric distress, dysuria, depression, vertigo, incoordination, ataxia, abdominal cramping, constipation, stomatitis, numbness or paresthesia of an extremity, joint pains, confusion, irritability, weakness, cystitis, pelvic pressure, dyspareunia, fever, polyuria, incontinence, decreased libido, nasal congestion, proctitis and pyuria. Elimination of trichomonads may aggravate candidiasis.

Dosage and Administration: *In women:* one 250-mg. oral tablet three times daily for ten days. A vaginal insert of 500 mg. is available for local therapy when desired. When used, one vaginal insert should be placed high in the vaginal vault each day for ten days; concurrently two oral tablets should be taken daily.

In men: When trichomonads are demonstrated, one 250-mg. oral tablet twice daily for ten days in conjunction with treatment of his female partner.

Dosage Forms: Oral tablets—250 mg.
Vaginal inserts—500 mg.

*Complete list of references on request.

SEARLE

Research in the Service of Medicine

...now fast relief of hay fever symptoms with

NTZ®

Nasal Spray

When pollens fly, just one or two squirts of NTZ in each nostril, followed in a few minutes by a second spraying, shrink swollen nasal passages almost on contact. And breathing comfort follows. The antihistamine component of NTZ helps combat the allergic reaction and lessen rhinorrhea, sneezing and itching; its antiseptic wetting agent promotes rapid spread of components.

NTZ Nasal Spray affords the well-known benefits of Neo-Synephrine® in a carefully balanced formula which includes:

Neo-Synephrine® (brand of phenylephrine) HCl, 0.5% (adult strength), decongestant
Thenfadil® (brand of thenyldiamine) HCl, 0.1%, antihistamine
Zephiran® (brand of benzalkonium as chloride, refined) Cl, 1:5000, antiseptic wetting agent

Treatments with NTZ should be repeated every three or four hours as needed. NTZ is for temporary relief of nasal symptoms and overdosage should be avoided. Available in squeeze bottles of 20 ml. and 1 oz. bottles with dropper.

YOUR INSPECTION INVITED • BROCHURE ON REQUEST

Your Pathologist

is a Practicing Physician Like Yourself —

Be Loyal To His Local Laboratory

Dear Doctor:

Our laboratory was established to provide the practicing physician with a private laboratory that maintains standards and quality control presently available only in leading medical centers. The laboratory is physician owned and operated.

Prominent consultants in academic medicine from the fields of clinical chemistry, microbiology, hematology, and cytology work actively along with our Directors, all of whom hold Doctorate degrees, to assure that all diagnostic services performed continue to meet the physicians' demands for quality laboratory results. Our laboratory is unique because our consultants are available to the referring physicians for interpretation and advice concerning unusual and interesting cases, as well as routine cases.

Our highly skilled technicians, modern equipment, and computerized procedures permit us to offer the most rapid service available. We provide the required supplies and containers (postage paid, if necessary) for all of our diagnostic services. In addition, specimen collection service is available in many areas.

We are dedicated to maintaining prices that are competitive, and we feel we offer more to the physician and his patients than any existing laboratory. Either patient or physician billing is available.

Please return the enclosed postcard for further information. Thank you for your time.

Yours truly,

When you read the above letter, and others similar to it which you receive from time to time, you just have to get *mad* . . . not angry . . . *mad!*

Pathology is the basis of good medicine, just as it was when all of us were medical students. Private physicians practicing pathology are the best professional friends doctors in private practice have. Their laboratories are the keystone of good medical practice. We have excellent pathologists and excellent physician-pathologist laboratories in Baltimore and the State of Maryland. This is why I get *mad*—and you should too!—when out-of-state laboratories malign the value of my local pathologist and his laboratory, downgrade the fellow physician-practitioner who helps me most to practice good medicine, and callously advertise for my referrals.

The laboratory that I use in Baltimore is physician owned and operated. It maintains standards and quality control above that presently available to me in leading medical centers, because it is tailored to my private patients needs, and is personalized in its relationship to my practice. My pathologist does not need Directors who hold Doctorate degrees to assure quality results because my pathologist *is* the director, and his MD degree and board certification in Pathology qualifies him to guarantee me quality results. If he needs conference regarding an unusual case, he has access to consultants in the University of Maryland and The Johns Hopkins hospitals where he is privileged to practice. He has highly skilled technicians. He does not need postage-paid containers for my patients because they report to his office, but he provides this service for out-of-area patients, provided he has a clinical history to go along with his tests. He has no interest in competitive "prices" and he does not send me a bill; he collects from the patient a fee for his services, just as does any other physician or surgeon consultant when I refer a patient.

Above and beyond everything else, my pathologist and his laboratory offers to me and my patients more than any other laboratory, and I bitterly resent the idea that this laboratory is paranoid enough to feel that it offers more than "any existing laboratory."

Every physician should realize that

(1) Pathology-laboratory medicine is the practice of medicine.

(2) Pathologists who own and operate private laboratories are consultants in the practice of pathology and laboratory medicine.

(3) Fees for service are due to these consultants as to any other specialist-consultant.

(4) The referring physician should *NOT* be billed for pathology-laboratory fees; other specialist-consultants (surgeon, cardiologist, etc.) do not bill the referring physician.

(5) The Pathologist in private practice is a practicing physician . . . be loyal to him, and to his *local* laboratory.

JOHN F. SCHAEFER, MD
Baltimore

Occipital Neurectomy in the Treatment of Headache

Results in 30 Cases

The primary treatment of any headache problem is, and properly should be, medical management. If a therapeutic response is not prompt and satisfactory, the next step is to investigate further whether or not an intracranial source of the chief complaint exists. When electrographical and neuroradiological studies prove to be normal and headaches persist, in spite of what should be a predictably efficacious program of medication, the patient is often, if not usually, told that his problem is psychosomatic—"tension . . . unrelieved hostility", or the like.

Psychic conflict and repressed aggression are so well recognized to be a competent producing source of pain in the cranial or cervical regions that expressions such as "a real headache" or "a pain in the neck" are used in all languages to describe or refer to situations or associations which inspire frustration, antagonism or rage. It is my belief, however, that the concept of "tension headache" has been so widely and thoroughly oversold that many patients are denied, thereby, the opportunity to obtain effective relief from headache-producing cranial or cervical neuralgias by surgical means.

Those sufferers from occipitofrontal headaches who are unresponsive to medicinal therapy, and whose complaints are not due to serious intracranial conditions, have a disorder known generally as "occipital neuralgia". While there is no doubt that in many of these patients the condition is psychosomatic, pain in a significant and salvageable number of this group is of traumatic, of cervical arthritic, or other organic cause and simple surgery will afford relief which is usually prompt, satisfactory, and of long duration.

J. PETER MURPHY, MD
Chief, Subsection of Neurosurgery
Suburban Hospital
Bethesda, Maryland
Associate Clinical Professor of Neurosurgery
George Washington University Medical School
Washington, D.C.

Thirty patients were operated upon in this series. Occipital neurectomy was performed on one side only in 18; bilateral neurectomies were carried out in 12. Seven patients were 60 years of age or older, four were in their fifties, eight in the forties, ten in the thirties, and one was 26-years-old.

The effect of surgery was considered to be excellent in 18 patients, good in 7, fair in 3 and poor in 2. Follow-up was for 15 years in 1 patient, 12 years in another, 5 years in 2 patients, 3 years in 1, 2 years in 7 patients, 1 year in four, and for less than 1 year in 14 patients (Table 1).

Table 1.—Statistics of series of 30 patients in whom occipital neurectomy was performed.

The presumed causes of occipital neuralgia in the series were varied, but in the majority of cases the cause was thought to be trauma, cervical arthritis, or both conditions. Three patients were recognized to be obviously neurotic, but failure of other treatment, resistance to psychotherapy, desire for relief, and suggestively positive results from preliminary xylocaine nerve block, prompted surgery. As might be anticipated, the result in one patient was adjudged to be only fair, in the other two, it was definitely poor.

Excellent relief was obtained, rather surprisingly, in two patients—the onset of whose neuralgia dated definitely to the time of thrombosis of a vertebral artery, which was verified by arteriography in one case, and was assumed to be true on valid neurological grounds in the other. Migraine of atypical location was causative of neuralgia in one patient; results were "fair" at best after surgery. Sinusitis gave origin to symptoms in a young man; after all neurological and neuroradiological examinations, relevant to the presence of brain abscess, were normal, xylocaine nerve block pointed the way to completely effective surgical relief by occipital neurectomy. The severe neck pain resulting from spasmodic torticollis was eliminated by removal of the ipsilateral occipital nerve in a 66-year-old man, although the primary spastic condition was, of course, not affected thereby. Post-mastoidectomy neuralgia necessitated surgical treatment for one patient.

A complicating problem of previous alcoholism—to the extent of two bouts of pancreatitis, chronically recurring hypertension, severe neurosis, and temporarily immobilizing cervical arthritis—in one patient would not bespeak a predictably satisfactory result from any type of surgery. Complete, although temporary, cessation of occipitocervical headaches following nerve blocks justified performing a bilateral neurectomy, with ensuing and enduring symptomatic cure!

A last patient merits description as an instructive curiosity: carcinoma of the lung had been resected six years before. When right occipital headaches became associated with nystagmus and ataxia, the clinical impression was that of metastatic carcinoma of the right cerebellar hemisphere, particularly since an abnormal x-ray of the chest revealed a widened mediastinum. While debate progressed as to the preferable form of definitive therapy, increase in headache demanded symptomatic relief. Xylocaine nerve block caused immediate cessation of pain, but it recurred as the effect wore off.

Several interesting events ensued (1) right occipital neurectomy relieved the original occipitocervical pain completely; (2) histological examination of the nerve bundle removed disclosed infiltration of metastatic neoplastic carcinoma; and (3) herpes zoster developed in the domain of the greater occipital nerve and in the right side of the forehead. It has long been known that occipital neuralgia and conditions causing it produce pain in the ipsilateral forehead and eye, as well as in the occipitocervical area. And it has been demonstrated experimentally in human volunteers that injection of an irritating solution into the second cervical nerve root evokes immediate pain in the ipsilateral fronto-ocular zone. The exact anatomical pathways from back to front have not as yet been elaborated, which suggests that such pain radiation is due to a cervical-trigeminal reflex at a brainstem level.

The production of herpes zoster in the patient after occipital neurectomy proves, at least to my satisfaction, that a branch of the second cervical nerve root and its occipital extension *must* supply the forehead area directly. Indeed, all of the patients of this series suffering from headaches of incontrovertibly major organic causes did complain of fronto-ocular radiation or onset of pain frontally. Absence of this component of the syndrome throws suspicion upon the accuracy of the diagnosis.

Auopsy of the carcinoma of the lung patient referred to discolosed metastasis to the *left* half of the cerebellum. Therefore, right occipital neuralgia could not have been a symptom of intracranial expansile irritation; and direct nerve infiltration was revealed histologically, as noted.

In a few patients, headache of a different type recurred after surgery, but it was so clearly differentiated by the individual that he did not become disappointed when he considered the benefit obtained by neurectomy.

Anatomy, Pathology of Occipital Neuralgia

Occipital nerve resection has been described in neurosurgical practice for many years. The definitive article on the subject of the surgical therapy of occipital neuralgia appeared in 1949, when Hunter and Mayfield discussed their experience with 11 patients and described relevant anatomical and pathogenetical considerations in this syndrome.[1]

The sensory component of the first cervical nerve root is meager. The roots of the third cervical nerve root are not subject to the compression of motion since they are well protected in their bony canals. But the sensory components of the second cervical nerve roots, the chief and only constituents of the greater occipital nerves, pass outwards or come in from between the posterior arches of the atlas and axis. Potentially, they are subject to traumatism, because of the forward-backward snapping of these structures or rotation of the head takes place between the atlas and axis, not between the atlas and the skull. These nerve roots are also vulnerable because they have no carapacial protection posteriorly, as do their homologues above and below.

The causative agents of occipital neuralgia in their order of importance are trauma, arthritis, and other conditions, such as inflammation or other tissue change which result in "nerve pinching." A notable and fascinating exception is thrombosis of one or more components of the vertebral-basilar arterial system. This type of thrombosis announces its presence by pain over the mastoid process on the same side as occlusion. Persistence of such pain in two patients in this series became a chief complaint.

In these cases, relief by occipital neurectomy is classic proof of "referred pain"—branches of the same second cervical sensory nerve root supplying the vessel and cutaneomuscular external fields.

Histological examination of the nerve specimens that were removed from the patients, disclosed neuromas in four, and infiltration by carcinoma in the one patient, which was described. The remainder of the biopsies appeared normal.

Surgical Considerations

Hunter and Mayfield divided the second cervical nerve roots intraspinally in some patients, and avulsed the greater occipital nerves in others.[1] In all of the patients reported here, avulsing external neurectomy of the greater occipital nerve or nerves was performed. The procedure proved to be adequate, and such surgery is simple, indeed, by comparison with intraspinal rhizotomy. The latter not only requires cervical laminectomy in the seated position, but may be and has been followed by the "progressive confusional syndrome", a formidable psychiatric complication also known to be the result of acute cervical traumatic conditions, such as a broken neck.

One or more linear incisions are made over the palpable grooves of the greater occipital nerves, which are equidistant between the external occipital protuberance and the mastoid process on either side of the posterior skull. If anatomical peculiarities are present, such as a short, fat neck, a transverse incision extending from mastoid tip to mastoid tip may be made instead, as in the performance of a cerebellar craniectomy. (Two detergent shampoos prior to skin preparation may obviate the necessity of shaving the scalp.) When the greater occipital nerve is glued to the occipital artery, which is very tortuous, hemorrhaging occurs sometimes. If it does, it can be controlled by electrocoagulation (Fig. 1).

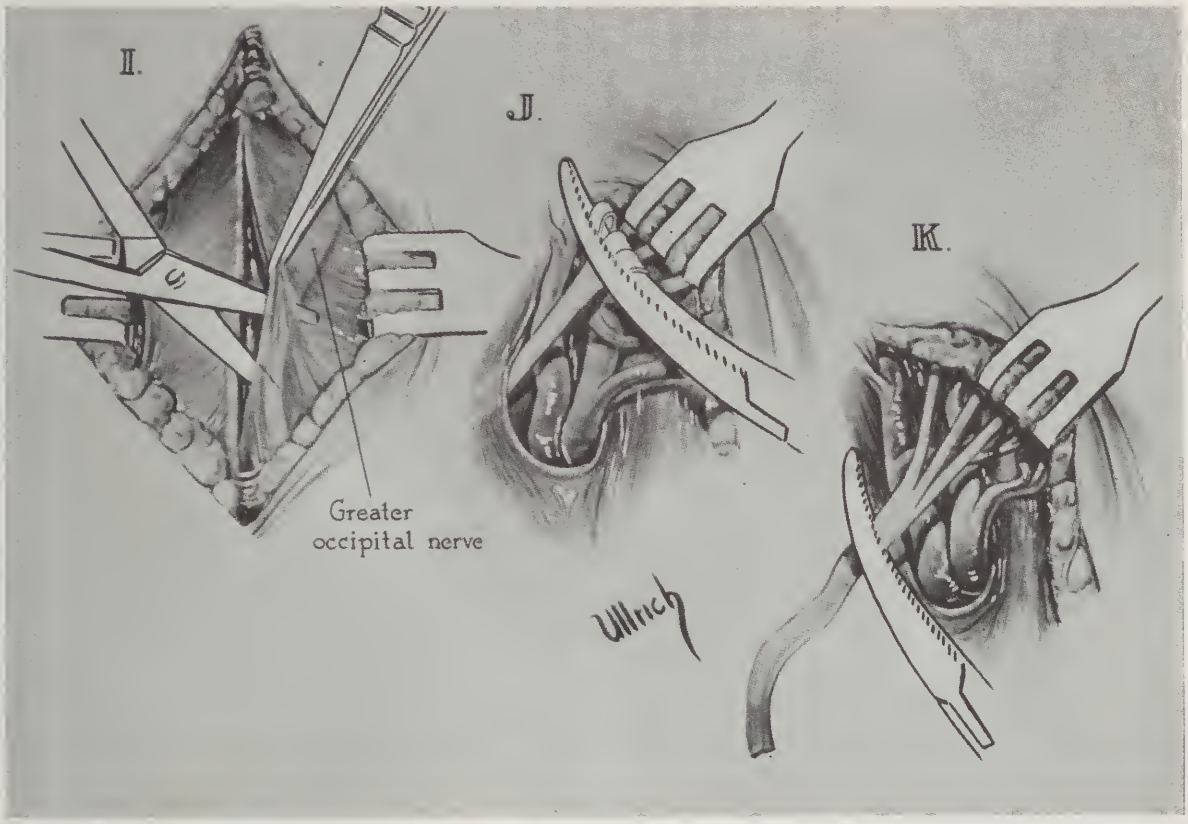

Fig. 1. Details of Occipital Neurectomy. (From Poppen, James L., "An Atlas of Neurosurgical Techniques", Published by W. B. Saunders Company, Philadelphia and London, 1960. Reproduced with permission of the Publisher.)

Experience demonstrates that it is not necessary to remove the minor occipital nerves, in addition to major occipital neurectomy in order to obtain a favorable result. There is, however, no reason not to take both sets of nerves if convenient. In one patient, minor occipital neurectomy had to be included since neuralgic pain was the consequence of previous mastoidectomy.

As much of the occipital nerves is avulsed as possible by twisting and pulling upwards on the axonal bundle with a hemostat. Sometimes, the length of nerve obtained gives pause to the surgeon who entertains the possibility of intraspinal cord damage, but this has never occurred in the experience of anyone, to the best of my knowledge. The occipital arteries may be divided (but not avulsed!) if pulsation is a part of the patient's chief complaint.

If regeneration of nerves after two to four years causes symptoms to recur, secondary surgery will be as effective as the primary procedure. (Reoperation was necessary in the patient whose pain resulted from a mastoidectomy scar.)

Loss of sensation after surgery is confined to the back of the head. At first, the area of numbness is extensive, but it soon contracts to a small island on one or both sides. Sensory limitation has not been considered to be troublesome by patients relieved of headache. Only two hospital days are usually required for surgical treatment. Stitches are removed in the office on the fifth postoperative day.

Diagnosis, Selection of Cases

Rather than rely upon psychiatric clearance in the selection of patiens for neurectomy to relieve occipital neuralgia, a positive diagnostic conformity is preferable. It is hard, if not impossible, to find anyone who does not have "problems."

In order to have a favorable prospect for occipital nerve surgery, the following criteria must be fulfilled in whole or in part: Typical pain must be reproduced by pressing over the homolateral occipital neurovascular bundle or by compressing the head or the neck with the vertex of the head tilted to the

painful side. The pain must radiate from the suboccipital or occipital area to the ipsilateral forehead or eye, or vice versa. There must be an adequate history of trauma, clearcut evidence of cervical arthritis, painful intracranial arterial thrombosis, or another competent producing organic cause of pain. Neurological signs of a valid conformatory type, such as loss of sensation or hyperalgesia of the skin area, presumably caused by the affected nerve must be observed. Nerve block with xylocaine or another comparable anesthetic must relieve pain, if it is said to be present at the time of injection. Such a nerve block was temporarily effective in all of the patients in this series, but was never effective permanently. It is extremely questionable that it ever is effective in a case of true occipital neuralgia of organic cause.

With reference to trauma, liabiility-favored, rear-end automobile collisions, with ensuing litigation still in process, must be weighed accordingly in deciding whether or not physical injury resulting from the accident is the principal cause of occipital neuralgia.

Needless to say, no patient in this series, who complained of pain in the back of the head, possibly originating within the cranium, was treated by peripheral occipital neurectomy until exhaustive diagnostic workup was completed, and was found to be normal. This included spinal puncture, EEG, x-rays of the skull, intracranial angiography, intracranial air studies, and cervical myelography which were carried out as and when conditions necessitated. All of the patients in this series were studied by one or more of these adjuvant techniques, in addition to clinical neurological examination.

Summary

Occipital neuralgia is a syndrome in which compression, injury, or other irritation of the occipital nerves on one or both sides of the head cause severe pain, which originates in the upper cervical and posterior parts of the cranium and radiates to the ipsilateral eye and forehead or vice versa.

A variety of symptoms such as, trauma and cervical arthritis are prominent and can be causative factors.

If the condition is physical in origin and evidences of an intracranial source of symptoms are lacking, occipital neurectomy, unilateral or bilateral as indicated, can produce long lasting relief from pain. Intraspinal rhizotomy was not necessary in any of the patients in the series reported here.

Careful analysis of presumably nonspecific or inorganic headache problems will reveal many patients who can benefit from this simple and curative operative procedure.

REPORTS

To The House of Delegates

The material contained in these Reports is informational only and does not reflect Faculty policy until such time as action is taken on them by the House of Delegates.

Recommendations and items contained herein are only up **for consideration** at this time.

COUNCIL AND EXECUTIVE COMMITTEE

Mr. President and Members of the House of Delegates:

The Council met at its regular stated intervals during the 1968-1969 year, as did the Executive Committee. Items of the most importance, and a summary of actions taken by both of these groups, are as follows:

Council: March 28, 1968;

PROFESSIONAL MEDICAL SERVICES COMMITTEE RECOMMENDATION ON PAYMENTS FOR MEDICAID INPATIENT AND OUTPATIENT SERVICES, EXCLUDING HOME AND OFFICE VISITS

The following recommendation was adopted by the Council:

> That payment for Title 19 patients for professional services rendered patients in inpatient and in outpatient departments of hospitals be made on the basis of Usual, Reasonable and Customary fees until such time as the funds appropriated for these purposes are depleted.
>
> It is expected that services will not be withheld by physicians when such a point is reached. However, it should be understood that physicians will continue to submit bills, even though payment may not be received for those services rendered to patients who have been certified by the State agency as being eligible for medical care services for whom the State under its Medical Assistance Program has assumed full financial responsibility.

It is to be made clear that this adoption of a position does not involve home and office care under the Title 19 program.

POLICY ON USE OF MARYLAND TUBERCULOSIS ASSOCIATION AND STATE HEALTH DEPARTMENT X-RAY SERVICES

The following recommendation of the Occupational Health Committee was adopted by the Council:

> The Medical and Chirurgical Faculty of Maryland supports the principle that industry, requiring pre-employment chest X-rays, should be encouraged to contract with a private radiologist whenever possible. The Health Department and the Maryland Tuberculosis Association should discourage the use of their facilities by industry for pre-employment X-rays where it is felt that such an arrangement with a private radiologist is feasible.

PARTICIPATION IN MEDICAID PROGRAM

A subcommittee named by the Council chairman to prepare a statement on the Faculty's participation in the Medicaid program made its report which, after discussion, an amendment was adopted as follows:

> The Council of the Medical and Chirurgical Faculty of the State of Maryland, at its January 1968 meeting, stated it would clarify at its meeting in March, 1968, its position in regard to the Medicaid program, after the conclusion of the 1968 General Assembly session.
>
> Inasmuch as the Governor and the Legislature have failed to meet their obligations to those citizens for whom the state has assumed financial responsibility, by not appropriating sufficient funds to provide for their medical care, the Council cannot endorse either the present or proposed Medicaid program.

Following adoption of this action and general discussion, it was agreed that appropriate Faculty committees meet with their counterpart groups of the dental and pharmaceutical societies, as well as any others, for the purpose of preparing for transmission to the Governor and members of the Ad Hoc Health Planning Committee, comments on the initial report of the Ad Hoc Health Planning Committee to the Governor.

Executive Committee, March 9, 1968:

CHIROPRACTOR ACTIVITY

The Executive Committee voted to recommend to the Council that the following Mediation Committee recommendations be approved:

(a) The Faculty obtain an injunction to prohibit the use of term "physician" by Chiropractors
(b) Obtain an injunction to prohibit Chiropractors using the technique of "testing" to mislead persons as to scope of their practice

It is understood that legal counsel will be present for this discussion so as to explain the mechanisms of this proposal, as well as possible cost, etc.

Council, June 6, 1968:

INJUNCTION AGAINST USE OF TERM "CHIROPRACTIC PHYSICIAN"

The Executive Committee had recommended endorsement of the Mediation Committee's proposal that the Faculty proceed in obtaining an injunction against the use of the term "Chiropractic Physician" by some Chiropractors.

Counsel explained that his fee would be charged on the basis of his court appearances, a rate of $150 per day, as well as any other *cost* incurred in connection with preparing and serving of the papers. He estimated this to be in the neighborhood of $100. The legal

research, etc., would be part of the services rendered under his retainer.

The Council voted unanimously that Mr. King be empowered to proceed along the lines of his outline and the funds be expended to accomplish this purpose.

PROHIBITION OF CHIROPRACTORS MISLEADING THE PUBLIC BY TECHNIQUE OF "TESTING"

Some discussion ensued in this connection. This was also a recommendation of the Executive Committee, as suggested by the Mediation Committee.

The Council voted that Counsel be empowered to investigate the possibility of obtaining injunctive proceedings in this area, if after exploration it was determined that it would be proper to do so.

The question was raised regarding liaison between the Board of Medical Examiners and the Faculty and suggested the possibility of having a Board member serve on or attend Council meetings. It was agreed this was no particular problem at this time because both Drs. Cohen and Mech are on the Board and the Council. This could be discussed at a future date, if necessary, and any necessary changes made in the bylaws.

FORMULARY SYSTEM FOR MEDICAID PATIENTS

The Council discussed at some length the question of approval of the principle of publication of a "Formulary System" for physician prescribing under the Title 19 program in Maryland. It was brought out that the Pennsylvania program was under consideration for adoption in Maryland. Adoption of this program would result in substantial financial savings in printing and publication costs, and staff time for both development of a formulary system as well as computer programming time.

It was then voted that the Council endorse the principle of a formulary system for use of physicians in prescribing medication for Medicaid patients—with the understanding that it is an "open" formulary, and that it will be developed and changed, as necessary, in full cooperation with the Medical and Chirurgical Faculty.

FACULTY REPRESENTATIVE ON NEWLY FORMED MEDICAL TISSUE DONATION COMMITTEE

The circumstances leading to the formation of this new group were outlined. The Faculty had acted as a catalyst to bring all interested parties together for the purpose of discussing the following:

> Providing a central registry where potential donors could (a) receive information on all aspects of tissue donation and (b) list themselves as having indicated their desires with respect to such tissue donations. In addition, the registry could list needs and requirements of those persons or institutions engaged in transplant or research activities in these areas; as well as conduct educational efforts in hospitals so that antemortem permission could be obtained for persons who were near death, instead of endeavoring to obtain postmortem permission from relatives.

The Council indicated its support of this concept and then voted to designate Russell S. Fisher, MD, as its representative. The Faculty designee would serve as chairman of the committee.

Executive Committee, July 18, 1968:

CONTINUED PURSUIT OF INJUNCTION PROHIBITING USE OF TERM "CHIROPRACTIC PHYSICIAN"

Counsel stated that there were some legal questions being raised in connection with this action of the Council and he would like some direction from the Executive Committee in this regard.

The main question was one of strategy. He believed that it would be better strategy to wait until the Medical Practice Act Revisions become law and then pursue this question.

In the proposed revisions, a clear definition of the term "physician" appears. This would strengthen the hands of the Faculty in this area, if it is approved by the General Assembly.

The Executive Committee concurred in delaying any further action on this subject until after the 1969 General Assembly meets.

Executive Committee, September 5, 1968:

ANESTHESIA STUDY GROUP ON STATE-WIDE BASIS

It is proposed by the Maryland Society of Anesthesiologists that the current study of anesthesia deaths carried out jointly by the Baltimore City Health Department and the Baltimore City Medical Society be expanded to a state-wide project, similar to the maternal and child mortality studies.

Approval of the Faculty is sought to make this a state-wide project. The Executive Committee approved extension of this to a state-wide basis.

Executive Committee, October 10, 1968:

WORKMEN'S COMPENSATION COMMISSION, PAYMENT OF USUAL, CUSTOMARY AND REASONABLE FEES

Mr. Sargeant reported that the Faculty was granted an informal hearing before the full commission on September 19, 1968; and following this, it had submitted a proposal that such be the policy of the Commission, with the understanding that those physicians desirous of treating Workmen's Compensation cases list their Usual, Customary and Reasonable Fees with the Commission. This would then permit the carriers to have some guidelines to use in making payment on bills submitted.

Since then, the physicians who treat between 60-70% of such cases in the Baltimore area held a meeting and have agreed to abide by the Fee Guide issued by the Faculty in 1966, and to submit a schedule for home and office visits under which they will operate. It has been suggested the Faculty inform the Commissioner of this information, but the Executive Committee decided that those individuals wishing to do so, jointly sign a letter to the Commission outlining their proposal.

Executive Committee, November 14, 1968:

MULTIPHASIC SCREENING

The chairman presented an outline of what Multiphasic

Screening covers. He also discussed a meeting that had been held with representatives of the Bendix Corporation. After considerable discussion and questions and answers, the Council adopted the following:

The Council authorizes the Ad Hoc Committee on Multiphasic Screening to continue its work with the Bendix Corporation, and expresses its interest in this program with the provision that the Council be kept fully informed so that it can approve or disapprove each recommendation.

The Council also requests that all Specialty Groups involved be kept informed of this activity and be invited to participate in the deliberations of the ad hoc committee.

After adoption of that motion, the following additional motion was adopted:

That the Ad Hoc Committee be recommended to consider other alternatives to sponsorship of the Multiphasic Screening Program.

During these deliberations it was emphasized that no corporate structure would be used to employ physicians; Bendix would be involved in the operation of the technical aspects of the program only.

DIRECT TELEPHONE LINES

On recommendation of the Pharmacy Liaison Subcommittee and the Mediation Committee, The Council adopted the following motion:

The Medical and Chirurgical Faculty of the State of Maryland opposes direct telephone lines between a physician and a pharmacy.

It is understood that the Maryland Pharmaceutical Association and the C & P Telephone Company will be advised of this policy decision.

In addition to these actions, the Council and Executive Committee made recommendations for appointments to various boards, committees, governing bodies and agencies of the state government. The Council also ratified a total of 38 requests for legal defense and notes that the number of requests for this service is increasing at an astronomical rate.

Recommendations for Emeritus Membership is made for the following, all at the request of the component society indicated:

Baltimore City Medical Society:
Jacob R. Jensen, MD
Leo Kanner, MD
S. Demarco, MD
C. W. Peake, MD
H. F. Bongardt, MD

Carroll County Medical Society:
Elizabeth Reese Wilkens, MD

Montgomery County Medical Society:
John N. Andrews, MD

Respectfully submitted,
JOHN F. SCHAEFER, MD, *Chairman*

SECRETARY

Mr. President and Members of the House of Delegates:

The position of Faculty Secretary carries with it many responsibilities, such as supervising the proper handling of the correspondence, and scheduling of meetings throughout the year. More than 500 such meetings were scheduled and held during the past Faculty year.

Minutes of various committee, subcommittee and other sessions were prepared, meeting notices mailed and permanent records maintained of all Faculty activities. Complete files on all such material are available at the Faculty office.

Respectfully submitted,
WILLIAM A. PILLSBURY, MD, *Secretary*

EXECUTIVE SECRETARY

Mr. President and Members of the House of Delegates:

The work of the Executive Secretary and the Staff is reflected in the activities of the various Faculty Committees. What is not indicated, however, is the volume of individual telephone calls, personal visits and visits to component medical societies throughout the State that do much to knit the membership together and make membership in the Faculty meaningful.

During the past year, meetings with my counterparts in other professional organizations in the state have been instituted. These are informal and are held on an irregular basis. Mutual experiences and solutions to problems are discussed.

Sessions with full and part-time executive secretaries of component societies were continued. This does much to cement the bonds of friendship between the state and many of its components. Not only are components made aware of our planning, but they are also aware of the vital and tremendous role the Faculty plays in contemporary affairs today.

Respectfully submitted,
JOHN SARGEANT, *Executive Secretary*

BYLAWS COMMITTEE

Mr. President and Members of the House Delegates:

The Bylaws Committee submits the following proposed changes in the Faculty's Bylaws:

1. Upgrading of the present Subcommittee on Medicine and Religion to a full Faculty committee:

The reasons given for this proposed bylaw change are that increasing moral and religious problems are foreseen with the expansion of heart and other tissue transplants, as well as determinations as to time of death. In addition, Medical and Theological Schools are considering seriously the expansion of their curricula to include Medical and Religious subjects.

Amend Article XI, by inserting new section 13 to read as follows:

Section 13. A Committee on Medicine and Religion shall be appointed by the President to consist of not less than six members. It shall be charged with maintaining liaison and effective lines of communication between physicians and clergymen leading to the most effective care and treatment of the patient and his family. It shall also endeavor to assist medical schools

and nursing schools in their educational endeavors, and shall be available to theological seminaries for similar assistance—all within the areas of medicine and religion combined.

2. At the present time, there is a conflict in the Bylaws dealing with the provision of legal defense in cases of alleged malpractice. Article III, Section 5, reads:

"Any member entitled to Physicians' Defense shall forfeit that right if his dues were not paid to his component society by January 31, in the year in which the alleged malpractice occurred, provided that new members admitted after January 31, shall be entitled to physicians' defense for alleged acts committed after the date their membership application is filed with the component society secretary."

Article VII, Section 2, reads, in part:

"The Council shall have all power and authority over the affairs of the House of Delegates, except modifying any action taken by the House of Delegates, and shall have power to: . . . authorize physicians' defense. . . ."

Article XII, Section 2 reads:

"On a majority vote, the Council may authorize physicians' defense and the matter shall be referred to an attorney-at-law retained by the Council for a term of one year."

Article III, Section 5, indicates that the physician *has the right* to physicians' defense, provided he meets the dues payment requirement. It does not give the Council discretion to determine whether or not this should be granted, although the other sections, Article VII, Section 2; and Article XII, Section 2, both seem to indicate there is discretionary power to deny or grant such defense.

In actuality, however, all legal defense cases are reported to the Council, which automatically ratifies the granting of defense. In order that the procedural activity be simplified, it is suggested that the following bylaw change be adopted:

Amend Article VII, Section 2, by striking out the following:

"authorize physicians' defense"

Amend Article XII, Section 1, by striking out:

"to the Council"

Amend Article XII, Section 2, by striking out:

"On a majority vote, the Council may authorize physicians' defense and the matter"

and inserting:

"Physicians' Defense Cases"

3. Forty-Year Members are not subject to dues. Frequently, such members may move from the State when they retire from active practice. There is no provision for retention of this status of membership. Presently, such members are required to be members of component societies in Maryland. They would, therefore, have to change to Emeritus Status or Affiliate Status.

It is, therefore, recommended that Forty-Year members be permitted to retain this status if they move outside of Maryland and the following bylaw amendment is recommended for adoption:

Amend Article II, Section 5, by adding the following new sentence:

"Forty-Year Members who have this status prior to removing from the State of Maryland may continue to hold this type of membership after their removal."

4. In accordance with the Semiannual Report of the Bylaws Committee, we are pleased to present the following bylaw amendment, in connection with the composition of the Faculty's Council:

Substitute for Article IV, Section 3, the following new section which reads as follows:

Section 3. One third of the COUNCILORS provided below shall be elected annually by the House of Delegates from among the active members of component societies comprising the following districts:

(a) Western District: Allegany, Garrett, Carroll, Frederick and Washington counties

(b) Eastern District: Caroline, Cecil, Dorchester, Kent, Queen Anne's, Somerset, Talbot, Wicomico and Worcester counties

(c) Central District: Baltimore city, Baltimore and Harford counties

(d) Southern District: Anne Arundel, Calvert, Charles, Howard and St. Mary's counties

(e) South Central District: Montgomery and Prince George's counties

Representation shall be on the basis of one Councilor from each district, plus one additional Councilor for each 200 active and Forty-Year Members in good standing on December 31 each year.

The adoption of this bylaw change results in Councilors for each district as follows:

Central District	1896 Members	11 Councilors
Eastern District	192 Members	2 Councilors
South Central District	728 Members	5 Councilors
Southern District	173 Members	2 Councilors
Western District	294 Members	2 Councilors

There is no change in the total number of councilors now on the Council.

PROPOSED BYLAW AMENDMENTS FOR PRESENTATION TO THE HOUSE OF DELEGATES APRIL, 1969

Amend Article XI, by adding new Section 13:

OLD	*NEW*
(No such section, except included as an optional Subcommittee appointment of Liaison Committee)	"Section 13. A Committee on Medicine and Religion shall be appointed by the President to consist of not less than six members. It shall be charged with maintaining liaison

and effective lines of communication between physicians and clergymen, leading to the most effective care and treatment of the patient and his family. It shall endeavor to assist medical schools and nursing schools in their educational endeavors, and shall be available to theological seminaries for similar assistance—all within the areas of medicine and religion combined."

Amend Article VII, Section 2 by striking out the phrase, "authorize physicians' defense."

OLD

Section 2. The Council shall have all power and authority over the affairs of the House of Delegates, except that of modifying any action taken by the House of Delegates, and shall have power to: (1) issue charters to component societies; (2) recommend assessments; (3) remit a member's dues or assessment; (4) approve the budget; (5) appoint one or more assistant secretaries or assistant treasurers; (6) fill vacancies among the elective officers and those appointed by it; (7) fix the date and place of General Meetings; (8) **(authorize physicians' defense);** (9) appoint an Editor of the MARYLAND STATE MEDICAL JOURNAL for a term of three years or until his successor is appointed; (10) set the amount of bond on the Treasurer, the premium to be paid by the Faculty; (11) retain counsel to the Faculty for a one-year period; and (12) select independent certified accountants to audit the Treasurer's accounts and report to the annual session of the House of Delegates.

NEW

Section 2. The Council shall have all power and authority over the affairs of the House of Delegates, except that of modifying any action taken by the House of Delegates, and shall have power to: (1) issue charters to component societies; (2) recommend assessments; (3) remit a member's dues or assessment; (4) approve the budget; (5) appoint one or more assistant secretaries or assistant treasurers; (6) fill vacancies among the elective officers and those appointed by it; (7) fix the date and place of General Meetings; (8) appoint an Editor of the MARYLAND STATE MEDICAL JOURNAL for a term of three years or until his successor is appointed; (9) set the amount of bond on the Treasurer, the premium to be paid by the Faculty; (10) retain counsel to the Faculty for a one-year period; and (11) select independent certified accountants to audit the Treasurer's accounts and report to the annual session of the House of Delegates.

Amend Article XII, Section 1, by striking out the words, "to the Council"

OLD

Section 1. Any qualified member who is the subject of a civil claim or suit for alleged malpractice, desiring to avail himself of the provisions of this Article, shall immediately make written request **(to the Council)** for physicians' defense setting forth a complete history of the case, the services rendered and his connection or relationship to the complainant.

NEW

Section 1. Any qualified member who is the subject of a civil claim or suit for alleged malpractice, desiring to avail himself of the provisions of this Article, shall immediately make written request for physicians' defense setting forth a complete history of the case, the services rendered and his connection or relationship to the complainant.

Amend Article XII, Section 2 by striking out the words, "On a majority vote, the Council may authorize physicians' defense and the matter" and inserting, therefore, the following: "Physicians' Defense Cases"

OLD

Section 2. **(On a majority vote, the Council may authorize physicians' defense and the matter)** shall be referred to an attorney-at-law retained by the Council for a term of one year.

NEW

Section 2. Physicians' Defense Cases shall be referred to an attorney-at-law retained by the Council for a term of one year.

Amend Article II, Section 5, by adding the following new sentence: "Forty-year Members who have this status prior to removing from the State of Maryland may continue to hold this type of membership after their removal."

OLD

Section 5. *FORTY-YEAR MEMBERS* shall consist of the active members in good standing of all component societies who have been active members for forty years or more. They shall have the rights accruing to active members.

NEW

Section 5. *FORTY-YEAR MEMBERS* shall consist of the active members in good standing of all component societies who have been active members for forty years or more. They shall have the rights accruing to active members. **Forty-year Members who have this status prior to removing from the State of Maryland may continue to hold this type of membership after their removal.**

Substitute for Article IV, Section 3, the following new section which reads as follows:

Section 3. One third of the COUNCILORS provided below shall be elected annually by the House of Delegates from among the active members of component societies comprising the following districts:

(a) Western District: Allegany, Garrett, Carroll, Frederick and Washington counties

(b) Eastern District: Caroline, Cecil, Dorchester, Kent, Queen Anne's, Somerset, Talbot, Wicomico and Worcester counties

(c) Central District: Baltimore city, Baltimore and Harford counties

(d) Southern District: Anne Arundel, Calvert, Howard and St. Mary's counties

(e) South Central District: Montgomery and Prince George's counties

Representation shall be on the basis of one Councilor for each district, plus one additional councilor for each 200 Active and Forty-Year Members in good standing on December 31 each year.

OLD

Section 3. One third of the *COUNCILORS* provided below shall be elected annually by the House of Delegates from among the active members of constituent societies comprising the following districts:

(a) Western District: Allegany, Garrett, Carroll, Frederick and Washington counties; **two councilors.**

(b) Eastern District: Caroline, Cecil, Dorchester, Kent, Queen Anne's, Somerset, Talbot, Wicomico and Worcester counties; **two councilors.**

(c) Central District: Baltimore city, Baltimore and Harford counties; **eleven councilors including at least eight from Baltimore city, two from Baltimore County and one at large.**

(d) Southern District: Anne Arundel, Calvert, Charles, Howard and St. Mary's counties; **two councilors.**

(e) South Central District: Montgomery and Prince George's counties; **five councilors; three from Montgomery County and two from Prince George's County.**

NEW

Section 3. One third of the *COUNCILORS* provided below shall be elected annually by the House of Delegates from among the active members of component societies comprising the following districts:

(a) Western District: Allegany, Garrett, Carroll, Frederick and Washington counties.

(b) Eastern District: Caroline, Cecil, Dorchester, Kent, Queen Anne's, Somerset, Talbot, Wicomico and Worcester counties.

(c) Central District: Baltimore city, Baltimore and Harford counties.

(d) Southern District: Anne Arundel, Calvert, Charles, Howard and St. Mary's counties.

(e) South Central District: Montgomery and Prince George's counties.

Representation shall be on the basis of one Councilor from each District, plus one additional councilor for each 200 Active and Forty-Year Members in good standing on December 31 of each year.

COMMITTEE ON CONTRACTUAL ARRANGEMENTS

Mr. President and Members of the House of Delegates:

No meetings of this group were held during the year. No complaints or requests were received and no problems arose that would involve the services of this committee.

Respectfully submitted,

J. Howard Franz, MD, *Chairman*
Robert Z. Berry, MD
Stanley J. Bociek, MD
Theodore Feldberg, MD
Paul F. Guerin, MD
Theodore Kardash, MD
John G. Lyons, MD
William J. McClafferty, MD
Elliott Michelson, MD
Thaddeus E. Prout, MD
Guy M. Reeser, Jr., MD
Albert Shapiro, MD
Charles E. Silberstein, MD
Henry H. Startzman, Jr., MD
Henry B. Wilson, MD
William A. Niermann, MD
James W. Smyth, MD

CURATOR

Mr. President and Members of the House of Delegates:

It gives me great pleasure to advise that donations of material and other equipment are continuing to be given to the Faculty, adding to our memorabilia.

During the last year, the following items have been received for the Faculty's collection. In each case, the donor has been suitably thanked, and the item has been recorded in the accession records of the Faculty. In some cases, the piece has been adequately displayed in the Faculty building for all to view.

Framed oil painting of Albert E. Goldstein, MD, a gift from his wife.

Suction machine, property of Moses Raskin, MD, a gift from his family.

Framed photographic portrait of Caleb Winslow, MD, a gift from his grandson, Mr. Caleb Winslow.

Doctorate robes, property of Walter D. Wise, MD, and Julius Friedenwald, MD, a gift from Mr. William McMillan, stepson of Dr. Wise.

As authorized by the House of Delegates, portraits are being restored and maintained in good condition. The sum of $500 per year is allocated for this purpose.

Respectfully submitted,
E. David Weinberg, MD

DELEGATES TO THE AMA HOUSE OF DELEGATES CLINICAL SESSION, DECEMBER 1-4, 1968, MIAMI BEACH, FLORIDA

Mr. President and Members of the House of Delegates:

The Faculty's three delegates to the AMA Clinical Session, held December 1-4, 1968, in Miami Beach, Fla., attended each session of the House of Delegates. In addition, the Senior Alternate Delegate and the Executive Secretary also attended each of these sessions. Assignments were made to the various Reference Committee hearings, so that full knowledge and discussion could take place in connection with all matters coming before the House. The resolution submitted by the Maryland Delegation (Resolution #5, Admission of Doctors of Osteopathy to full Active Membership in the AMA) was adopted by the House of Delegates. An appropriate bylaw amendment will be acted upon at the Annual Session in July 1969, in New York city. Actions of the House of Delegates included the following:

Discrimination

The Council on Constitution and Bylaws presented wording for the anti-discrimination amendments in response to the House's wishes expressed at the Annual Convention in June 1968.

The over-all statement on discrimination was added as a new Section 3 of the bylaws, Chapter I:

> Section 3—Discrimination in Membership
> Membership in the American Medical Association or in any of its constituent associations shall not be denied or abridged on account of color, creed, race, religion, or ethnic origin.

Provision for disciplinary action was provided by adding this sentence to Chapter XI, Section 11, (D) (7):

> If the Council determines that the allegations (of discrimination against physician applicants for membership) are indeed true, it shall admonish, censure, or, in the event or repeated violations, recommend to the House of Delegates that the state association involved be declared to be no longer a constituent member of the American Medical Association.

Osteopathy

The House adopted a Board report stating these objectives with respect to osteopaths:

To "assure the provision of the best possible health care to the American people; make available to students and graduates in osteopathy, education of the same high standards as prevail in undergraduate, graduate, and continuing educational programs in medicine; provide avenues whereby qualified osteopaths may be assimilated into the mainstream of medicine."

To achieve those objectives, the AMA recommends that each school of osteopathy improve its teaching program by strengthening its faculty and improving its facilities and resources; invites schools of osteopathy and their accrediting agencies to consult with the AMA and the Association of American Medical Colleges; suggests that accredited hospitals may accept qualified osteopaths on medical staffs; suggests that medical specialty boards may accept osteopaths for examination if they have com-

pleted AMA-approved internships and residency programs, and have met other regular requirements; requests that as specialty boards declare intent to permit examination of osteopathic graduates, appropriate AMA-approved residency programs be opened to qualified osteopathic graduates; suggests opening AMA-approved internships to qualified osteopathic graduates; recommends that determination of qualification be made at the level of the medical staff, the county medical society, or the review committees and boards having appropriate jurisdiction; and suggests that AMA, state and county societies and other affected organizations "may proceed to make such constitution and bylaw changes as are necessary to implement the foregoing."

The House also "suggests that each county and state medical society may accept qualified osteopaths as active members and thereby provide for their membership in the American Medical Association" and instructed the Council on Constitution and Bylaws to prepare "appropriate bylaw amendments so that qualified doctors of osteopathy may be admitted to full active membership" in the AMA. (This was the resolution submitted by the Maryland delegation.)

Awards

J. Arnold Bargen, MD, of Riverside, California, was chosen to receive the AMA Distinguished Service Award, which will be presented at the 1969 Annual Convention.

John D. Rockefeller, III, of New York, Chairman of the Board of the Rockefeller Foundation, was selected to receive the Citation of a Layman for Distinguished Service, also to be awarded at the Annual Convention in July 1969.

President's Report

Dwight L. Wilbur, MD, President, told the House that "Perhaps our greatest problem is that, in many ways, we in America have tried too hard and succeeded too well . . . We have progressed so far in so many areas that our people are impatient with the realities of human limitation. They are eager to instantly wipe out poverty, eliminate ignorance, sweep away ill will and violence, replace jealousies and hate with universal good will. Even the specter of death itself is by some considered a temporary and stubborn spite to mankind that will be mastered as soon as new organs are developed or transplanted and new drugs are synthesized."

President Wilbur listed five areas to which he believes the medical profession should give its greatest attention:

1. Making high-quality health care available for everyone in America at as reasonable a cost as possible.

2. Putting a rein on costs by avoiding hospitalizing any patient unless absolutely necessary; reducing the length of hospital stay to the essential minimum; using extended care facilities, nursing homes, and home-care services more often; stimulating prepayment mechanisms on a voluntary basis; supporting the principle of income tax credits for health insurance; keeping physicians' charges on a basis of usual, customary, and reasonable fees, with self-discipline and peer review; and encouraging wider use of reliable automated laboratory procedures, passing the cost benefits on to patients.

3. Developing more reasonable and more realistic expectations by the public.

4. Unifying the medical profession and maintaining constructive liaison between other groups.

5. Planning for an orderly and enhanced future. "We must," he said, "increasingly depend on the Board of Trustees to lead in planning and development for the future. . . . As an association, this is our greatest responsibility. The Board must increasingly be an informed board of strategy that looks ahead and advises the profession, the government, and the public regarding health measures."

The President closed his report by saying, "We are immersed in an epoch of change. We cannot hope to emerge from it as respected leaders unless we guide the course of change. . . . Our guidance in helping change all elements of society that affect the people's health is an orderly, balanced sequence which is the price of our continued esteem as a profession and an organization."

Organ Transplants

The House adopted a statement on heart transplantation which makes these five points:

1. The preservation of good medical practice demands that the evolution of therapy be orderly. "The staff of a hospital or medical center planning to initiate such a program should have: (1) adequate background in animal research so that experience is gained as to the problems, potentials, and limitations of cardiac transplantation; (2) experience in immunotherapy and an adequate source of antilymphocyte globulin of known quality; (3) a protocol of clinical research adequate to follow and evaluate the course of the patient."

2. Due regard for the welfare and safety of each individual patient is paramount.

3. Heart transplantation has brought certain medical, ethical and legal questions into critical focus. "Paramount among them is the determination of death. The right of the prospective donor to the best possible medical care—a right which his potential role as organ donor must not be allowed to abrogate—must remain sacred. The growing ability of medical science to maintain some form of biological function for prolonged periods adds to the difficulty of defining the point of irreversible dissolution.

"The cause of death must be evident and of irreversible type. The fact of death must be established by adequate, current and acceptable scientific evidence in the opinion of the physicians making the determination. The determination of death in organ donors must be made by no less than two physicians not associated with the surgical team performing the transplant."

4. The potential for heart transplantation, whatever that may prove to be by subsequent clinical experience, will be "severely limited by the shortage of potential organ donors. . . . Basic research into the causes of heart disease and of hypertensive vascular disease is . . . of vital importance, since the only ultimate solution to the problem of heart disease lies in its prevention."

5. "Human heart transplantation has been accompanied from the outset by a degree of public awareness and attention almost without parallel in medicine. . .

It is imperative, therefore, that the public be made fully aware of the potentialities and limitations of heart transplantation as those are currently understood and as that understanding is modified by subsequent experience. . . . Only by preserving public confidence in the judgment of the physician, can the orderly progress of medicine be maintained."

The House also approved the Uniform Anatomical Gift Act and urged each state medical association to give it careful consideration "with a view to seeking its adoption in its state." State associations were urged to consider carefully the provisions of the legislation and to make any necessary changes to accommodate their needs. The Uniform Act has been approved by the American Bar Association through the Liaison Committee to the ABA and the House supported cooperative efforts by state medical associations and state bar associations to secure prompt adoption of the legislation. (Maryland has already adopted an almost identical law.)

Health Care Costs and Financing

Following its similar action at the 1968 Annual Convention, the House again accepted for information the report of the Committee on Health Care Financing pertaining to the use of federal income tax credits for the purchase of health insurance and adopted a resolution that the AMA "vigorously promote the enactment of federal legislation which would translate the concept of income tax credits for health insurance premiums into law."

The House asked the Board of Trustees to devote sufficient staff, facilities and funds to develop an "effective program for immediate and on-going studies of health care costs" and to report the status of the program at the 1969 Annual Convention. The Board also was requested to expedite and expand existing programs and, "where necessary, develop new programs for the following purposes: (1) analysis of health care costs and expenditure data developed and reported by other sources; (2) definitions, reports and explanations of the several major categories of health care expenditures; and (3) dissemination of the data, findings and conclusions of such studies to constituent medical societies, news media and state and federal governmental authorities."

Recognizing that advertising and promotion of new Blue Shield programs providing broader benefits might be subject to misinterpretation by the public, the House resolved that "any references to 'paid-in-full' coverage clearly identify those services which are indeed covered on a 'paid-in-full" basis and also identify the circumstances under which those services must be rendered."

In two other actions, the House called on "all voluntary health insurance organizations to offer reinstatement of all contracts which were cancelled or converted because the insured individual was over age 65 and eligible for" medicare; and reaffirmed the AMA's belief that "the concept of voluntary health insurance is the most acceptable means of financing health care when applied in keeping with the principles of the American Medical Association."

Matters of Patient and Public Interest

The House adopted the Council on Medical Education's "Special Requirements for Residency Training in Family Practice" and resolved that the AMA "affirm the importance of providing appropriate recognition for family physicians through approval of a primary specialty board for family practice and that the Council on Medical Education be encouraged to continue its efforts with the American Academy of General Practice and the AMA Section on General Practice to achieve this goal."

In other actions, particularly aimed at patient care and public well-being, the House:

. . . Accepted for information a report that a portion of the Third National Congress on the Socio-Economics of Health Care would be devoted to solo practice.

. . . Adopted a report on the AMA's continuing concern with obesity treatment.

. . . Adopted a report stating that the AMA has proposed to the National Center for Health Statistics a meeting among concerned groups to review a revised certificate of live birth.

. . . Endorsed in principle the use of a multi-purpose health record form in providing medical examinations for young people.

. . . Resolved that the AMA "again urge its members to play a major role against cigarette smoking" and that the AMA "take a strong stand against smoking by every means at its command."

. . . Noted reports by "experts in recognized medical centers of new therapeutic uses of 'old' drugs which may be indicated in patients currently under the care of the physician" and resolved that the AMA discuss this problem with the Commissioner of Food and Drugs in an effort to enable the practicing physician to employ such new, life-saving therapy legally when indicated.

. . . Encouraged the American Association of State Highway Officials and the Federal Highway Administration to work toward the adoption of the International System of Highway Signs which avoids the use of language in order to make the visits of foreigners to the United States "as safe and pleasant as possible."

. . . Urged constituent societies in those states where existing laws do not permit minors to consent to treatment for venereal and other communicable diseases "to seek the enactment of such legislation." (Maryland already has such legislation; having taken the initiative on this subject over two years ago.)

Education

The House adopted a report of the Board of Trustees offering its comments (approval or suggested amendments) on many of the recommendations of the Report of the Citizens Commission on Graduate Medical Education. However, the Board pointed out that "it is neither possible nor desirable to make final recommendations . . . at this time on some of the more controversial portions of the report. These portions deserve further careful study and deliberation by all concerned individuals, institutions and organizations."

A program for formal recognition by the AMA of physicians who participate in continuing medical education was adopted, along with a proposal to fund the recognition award.

"A physician may, upon request," the report said, "receive the recognition award at the completion of three

years of graduate training in AMA-approved programs, or the equivalent in research activity or in educational programs leading to further advanced degrees in medical sciences."

Funding will include a registration fee of $5 for each physician who wishes to participate. The fee would cover the costs of printing, handling, mailing and processing the correspondence and certificates as well as the costs of initiating and maintaining the record system. Each physician would pay the registration fee only once in each three-year period.

The House recommended that the Medical Education for National Defense Program "be reinstituted at the earliest possible date; direction be the responsibility of the Department of Defense; adequate financial support be provided with appropriate safeguards to assure that funds will be used solely for the purposes of the program; and that such support be allocated to the medical schools on the basis of program merit."

And the House also encouraged the creation of continuing high quality service-career physicians "through specific support of existing medical school expansion to include selected, service career-oriented students."

Allied Health Personnel

The House agreed with the Council on Health Manpower regarding the need for physician prescription and supervision of all ancillary services provided in the hospital by adopting a Board of Trustees report on the utilization of paramedical personnel. In adopting the report, the House stated that "the medical staff should concern itself with contractual agreements between various allied health professionals and the hospital only insofar as, and to the extent that, such agreements tended to remove the provision of ancillary services from the prescription and supervision of the physician."

Another Board report adopted by the House, based on findings of the Council on Health Manpower, considered the phrase "related healing arts" as used in the declaration of purpose in PL 89-749. The report stated that "it is apparent that the context in which this term is used offers assurance that the patterns of medical practice in the country will not be altered by PL 89-749." Consequently, the Council recommended "that any definition of the term 'related healing arts' should be made at the state and local level because of the important variations in practice within the country."

The House adopted the Council on Medical Education's revision of "Essentials of Approved School of Medical Technology" and its "Essentials of an Accredited School of Radiation Therapy Technology."

In regard to nurses, the House resolved that "state and county medical societies be encouraged to study the problems relating to nursing education and to seek at the local level all available sources of financing support for hospital nursing schools" and that the AMA "take appropriate action in consultation with professional nurses' associations and the American Hospital Association to encourage increasing enrollment in diploma schools."

Medicine and the Government

The House accepted for information reports of the Council on Medical Service regarding neighborhood health centers under the Office of Economic Opportunity, Public Health Service, and Housing and Urban Development and Project Headstart.

In addition, the following resolutions were adopted by the House:

. . . That the AMA "seek to have Congress phase out Federal health care programs which overlap and reduplicate Medicaid."

. . . That PL 89-749 be amended to require that "a substantial percentage" of executive boards or councils "at all levels of planning—Federal, state and regional—both A and B agencies, be actively practicing private physicians nominated by organized medicine."

. . . That county and state medical associations, through the AMA, supply when requested, "the names and biographical data of physicians who are qualified, willing, and able to accept appointment in government service, full or part time."

. . . That the Board of Trustees "consider sponsorship of periodic conferences or workshops on public affairs for the continuing education and benefit of medical society leaders and physicians throughout the nation."

. . . That the AMA "exert every effort to bring about the elimination of unnecessary documentation of medical services by the physician, hospital and fiscal intermediary on Medicare and Medicaid patients."

. . . That all school administrative bodies be encouraged to consult with "competent medical authorities prior to initiating and conducting programs involving any medical aspects funded under the Elementary and Secondary School Act."

. . . That "physicians and their medical societies should strive to attain the adoption of established principles which are designed to provide the people of this nation with the highest quality of medical care" and that all physicians be reminded "that as free men and women they have no obligation to accept employment and remuneration under any conditions other than those arrived at by agreement between the physician and the recipient of his service."

Mostly of Internal (AMA) Interest

State and county medical societies were urged to establish uniform membership classifications based on AMA membership categories described in the bylaws. (Maryland has already done this.)

The Board of Trustees was asked to consider seriously recommending to the House that the 1976 Clinical Convention be held in Philadelphia as a part of the bicentennial celebration of the Declaration of Independence.

The House accepted for information a report that the Council on Medical Service has reconstituted its committee structure to provide for committees on Health Care Financing, Government Medical Services, and Community Health Care.

A report on the AMA-ERF and a special financial report on the Institute for Biomedical Research was adopted by the House, along with a resolution that a liaison committee of 10 members of the House "meet during the time of each convention of the House, or more often if necessary, with the President and Directors of the AMA-ERF and the Director of the Institute for Biomedical Research for review of current programs

of the AMA-ERF and consideration of suggestions for broadening the base of support for the AMA-ERF, and to report the results of such meetings to the House at each convention."

Dr. George W. Beadle, former president of the University of Chicago, was introduced to the House at the opening session, which took place on the day Dr. Beadle assumed directorship of the Institute.

A progress report on the management survey of the AMA, which is now under way, was adopted by the House. Also adopted was a resolution that "the Board of Trustees be requested to continue to observe closely the activities of the Division of Public Affairs since this division is newly formed with newly defined functions and activities; and . . . that the House of Delegates receive in advance a comprehensive report on the management survey and its implementation from the Board of Trustees prior to the next Annual Meeting."

The House recommended to the Board that "the office of Executive Vice President be filled, if possible, by a doctor of medicine who is an active member of the American Medical Association at the time of his appointment and who possesses the necessary managerial qualifications."

The House resolved that "the Executive Vice President prepare a report for the sessions of the House of Delegates as frequently as necessary but at least for each annual meeting and that the report be submitted in written form and referred to the appropriate Reference Committee" and that he be prepared "to present a brief oral summary of his report on request of the House."

Other resolutions adopted included these:

. . . That the Scientific Sections maintain responsible and responsive relations with all appropriate specialty societies.

. . . That the Board continue and expedite "its present activities to study and search for solutions to problems of medical professional liability."

. . . That the AMA, through its representatives on the JCAH, "take action to assure that accreditation be granted only to those institutions where the rights of the medical staff are not abrogated."

. . . That every county and state medical society initiate and maintain a "continuing program of active liaison between students at medical schools within their jurisdictions, preferably through active functioning chapters of SAMA."

. . . That the House go on record "favoring exploration of" establishing more uniform reciprocity arrangements among all states with respect to physican licensing.

. . . That the AMA adopt the following definitions and distribute them to all state medical associations for their individual consideration and guidance: " 'Usual' is defined as the 'usual' fee which is charged for a given service by an individual physician in his personal practice (*ie,* his own usual fee); 'Customary' is defined as that range of usual fees charged by physicians of similar training and experience for the same service within a given specific limited geographic or socio-economic area; 'Reasonable' is defined as a fee which meets the above two criteria, or, in the opinion of the responsible local medical association's review committee, is justifiable in the special circumstances of the particular case in question."

The House also resolved that "whenever these terms are used in contracts or laws, that they be specifically defined in those documents."

Miscellaneous Actions or Reports

M. Louise C. Gloeckner, MD, delegate from Pennsylvania and the only woman in the House of Delegates, received a standing ovation and a bouquet of roses from the House at its opening session. She ended her service in the House with this meeting.

Aubrey Gates, executive assistant in the office of the executive vice president and former director of the Field Service Division, was extended "recognition and commendation" by the House in advance of his retirement in May, 1969.

A report on the Woman's Auxiliary was given to the House by Mrs. C. C. Long, president; one on AMPAC was presented by Blair J. Henningsgaard, MD, AMPAC president; and Alvin J. Ingram, MD, secretary of the Board of Trustees, reviewed the Association's Annual Report from the delegates' handbook.

Memorial resolutions were adopted for L. Howard Schriver, MD, Ohio, and W. Benson Harer, MD, Pennsylvania.

Remarks of the Former Executive Vice President

Following the adoption of three resolutions commending F. J. L. Blasingame, MD, for his services to the AMA as delegate, trustee and executive vice president, Dr. Blasingame addressed the House briefly at its opening session.

He called for a constitutional convention to re-evaluate the working of the AMA to equip it better for the "Herculean tasks" it faces, adding that the existing committee system is inadequate for the work. "This is a time for action, clarification and soul-searching for the AMA," he said, adding that the Association "can't afford to be concerned with internal bickering."

Dr. Blasingame said several questions should be asked by the AMA of itself, including these: How can the organization discharge its primary obligation as advocate of physician responsibility? Is the organizational structure adequate to meet the obligations of modern science? How can priorities be established to help both the physician and the patient? How can a dichotomy be avoided between the scientific and political aspects of medicine?

By a vote of the House, Dr. Blasingame's complete remarks will be published in the Proceedings of this Clinical Convention.

COMMITTEE ON EMOTIONAL HEALTH

Mr. President and Members of the House of Delegates:

The Committee on Emotional Health has discussed and approved the recommendation of the Subcommittee on Drug Abuse for a drug abuse treatment center which would act as a liaison office for physicians and addicts and as a treatment facility.

Effort has been made to urge the members of the Maryland Psychiatric Society to join the Medical and Chirurgical Faculty.

The committee also continued the study of the psychiatric treatment facilities available for children in the State of Maryland. As a result of this study, it was suggested that the Faculty support the Department of Mental Hygiene's request for more facilities and that it support Senate Bill 80 (1969) which allows for school boards to provide mental health services through the school systems.

Members of the committee met with Delegate Rosalie Abrams to discuss an emergency commitment bill for psychiatric patients.

The committee considered and made recommendations to the Postgraduate Education Committee concerning an addendum to be added to the Interpretation of Legal and Ethical Requirements for Hospital Staff Performance of Therapeutic Abortion.

The committee studied the Revised Mental Hygiene Laws and other legislation concerning mental health, which was introduced in the 1969 State Legislature, and appropriate action was taken.

The committee reaffirmed its position of encouraging general hospitals to develop services for psychiatric patients.

Respectfully submitted,

THURMAN MOTT, JR., MD, *Chairman*
JAMES CARSON, MD
IRVIN H. COHEN, MD
AUGUSTO J. ESQUIBEL, MD
IRENE L. HITCHMAN, MD
JOHN LERTORA, MD
RICHARD H. PEMBROKE, JR., MD
ERNEST E. HARMON, MD
ISADORE TUERK, MD
JOSEPH J. REIDY, MD
VIRGINIA HUFFER, MD
EXALL L. KIMBRO, JR., MD
ALBERT A. KURLAND, MD

SUBCOMMITTEE ON DRUG ABUSE: ALBERT A. KURLAND, MD, *Chairman,* WILLIAM E. ABRAMSON, MD, EMMETT P. DAVIS, MD, JAMES D. DRINKARD, MD, STEPHEN A. HIRSCH, MD, JULIAN W. REED, MD, ADDISON W. POPE, MD.

FINANCE COMMITTEE

Mr. President and Members of the House of Delegates:

The Finance Committee met with a representative of the T. Rowe Price Company and reviewed the investment portfolio of the special dedicated funds of the Faculty. Every security was reviewed individually.

In 1968, $63,000 of the Coggins Building Fund was placed under the counsel of T. Rowe Price. This addition, plus investment growth of 9.9% during the year, brought the total market value of the portfolio to $1,095,630 by December 31, 1968. The approximate income of the portfolio was $32,587. The yield on invested capital was 3.6%.

Due consideration was given to recommendations by T. Rowe Price to trade certain securities. A motion to follow the recommendations was unanimously passed, and T. Rowe Price was instructed to effect the necessary transactions.

The 1968 portfolio accomplishment was quite favorable when compared to all of the well-known financial indicators.

Respectfully Submitted,

KARL F. MECH, MD, *Chairman*
M. MCKENDREE BOYER, MD
E. W. DITTO, JR., MD
W. KENNETH MANSFIELD, MD
THEODORE OSIUS, MD

MED-CHI INSURANCE TRUST

Mr. President and Members of the House of Delegates:

The Med-Chi Insurance Trustees have met frequently during the year in their effort to continually improve the various programs administered by the Trust. The Trust now administers the following programs: (1) Accident & Sickness Disability Insurance (2) Major Medical Expense Insurance (3) Blue Cross and Blue Shield (4) Business Expense Disability (5) Life Insurance and (6) Keogh Retirement plan. Other types of programs are also under study, including a casualty package and automobile coverage.

The Accident & Sickness and Major Medical programs were liberalized in May 1968, as a result of good experience since their inception in 1965. Participation has increased significantly during the year. The Trustees are now working toward an even more liberal program for the members.

The Rates of our Blue Cross and Blue Shield group are lower than any other standard 30-day group program. Participation has increased substantially, and hopefully our rates will remain the best available.

The Life Insurance subscribers were recently sent a cash dividend of 9%. Beginning with July 1, 1969, the subscriber will have the option of taking a cash dividend or a higher dividend to be applied against the insurance premium. This program has also grown in participation.

The Med-Chi Members Retirement Plan has just completed its first year in operation. The results of its operation during the year are most gratifying. As of December 31, 1968, there were 322 participants in the plan. The equity fund had a market value of $579,864. The fund growth was 19.9% over the year period, which was over four times the accomplishment of the Dow Jones Average.

We feel that all of our programs are financially sound and the most economical available for the members of the Faculty. It is our hope the programs will continue to receive the enthusiastic support of the membership.

Respectfully submitted,

PAUL F. GUERIN, MD, *Chairman*

MARYLAND STATE MEDICAL JOURNAL

Mr. President and Members of the House of Delegates:

On May 13, 1968, a meeting of the Editorial Board was held. During this meeting the subject of a new format for the JOURNAL, specifically a new cover design, was discussed and many of the proposals were adopted and have been incorporated in the publication.

We are no longer suffering from a manuscript insufficiency due to the efforts of the staff, and the quality of the papers submitted for publication has been, on the whole, unusually high.

Richard L. Masland, MD, resigned from the Editorial Board and was replaced by Wilber R. Ellis, Jr., MD. At the end of December, the term of Houston S. Everett, MD, was completed and Edward S. Klohr, MD, was appointed to his position.

Because of the increasing scope of the JOURNAL, now in its 18th year of continuous publication, a new staff position was created for an editorial assistant.

During the year, the JOURNAL has received a number of favorable criticisms from the membership regarding its new look. It appears that we are reaching more of the membership than in previous years.

Respectfully submitted,

C. Thomas Flotte, MD, *Editor*
Judy Sowell, *Managing Editor*

LIBRARY AND HISTORY COMMITTEE
FINNEY FUND COMMITTEE

Mr. President and Members of the House of Delegates:

During the calendar year the library has continued to increase its acquisitions in books particularly, while weeding out and discarding obsolete titles under the supervision of Mr. Lee Ash, library consultant. This program will account for a decrease in number of books now held by the library, since the number of volumes withdrawn from the collection exceeds the number of new volumes added. However, this readjustment indicates a definite revitalization of the book collection, eventually leading to a more viable library of current publications, while retaining the valuable collection of our rare books, history of medicine, manuscripts and incunabula.

The staff status remained approximately the same as in 1967, with the addition of one professional part-time librarian, Miss Sarah Katzoff, who had previously worked only during summers.

During the year, Mrs. Sanford, librarian, attended the national meetings of the Special Libraries Association in Los Angeles, the Medical Library Association, Denver, Colorado, regional meetings of the Middle Atlantic Medical Library Association in October, and the D.C.-Delaware-Maryland Hospital Association, Washington, in December.

At the Hospital Association meeting she participated in a panel discussion titled *"How* to get *what* you want *when* you want it." Other speakers represented the National Library of Medicine, the Medical College of Virginia at Richmond and the Baltimore Hospital Librarians' Association, sponsor of the meeting. This was the first program for medical and hospital librarians at the annual Tri-State Hospital Association meeting and probably will be continued since it was well attended and the group seemed enthusiastic.

Very little equipment was added during the year, the total being one new typewriter, a two-drawer file cabinet for periodicals acquisitions, and a small reference table for use at the abstracts and index shelves. No large items of furniture were purchased, pending removal of the large table from the reading room.

The exhibits and collections of books for the annual meetings were manned, as usual, by a professional librarian or Library Committee member at all times. Also, again the library cooperated with the committee on sports medicine by preparing a new updated bibliography on the subject for their Seminar on Sports Medicine held at Catonsville Community College in August.

Several meetings were attended by the librarian to discuss the status of the Middle Atlantic Regional Medical Library. The first was an all day session held at the National Library of Medicine with librarians from Welch Medical Library; Health Sciences Library at the University of Maryland; The Medical College of Virginia School of Medicine, Richmond; University of Virginia Medical School at Charlottesville; University of West Virginia School of Medicine; Georgetown University Medical School; George Washington University School of Medicine, and staff members from the National Library of Medicine. This was followed by another session after all participants had prepared working papers outlining their possible contributions to the motivation of an effective regional medical library in this area. The consensus of the second group was that nearly all libraries concerned would be able to increase their services only with additional personnel and funds for enlarged operation. The three major medical libraries already carry a considerable portion of the interlibrary loan and reference service in Baltimore and the surrounding areas. The National Library of Medicine services, on a rush basis, requests for items not available locally as a special accommodation in lieu of an official regional medical library such as most of the other regions now have.

Mr. Lee Ash has continued his consultation services during the year, finding many valuable items in need of repair, binding, or just plain salvaging. He will probably need most of next year to finish his survey; then the rare books and history of medicine libraries can be organized in one area—and hopefully in a more suitable environment than is now available. At present, a grill has been installed on the fourth stack so that this collection can be more securely housed.

MARYLAND MEDICAL SERVICE, INC. BOARD OF TRUSTEES

Mr. President and Members of the House of Delegates:

Again in 1968, the Maryland Blue Shield Plan recorded significant progress in all phases of its operations—enrollment, claims processing, general administration, and physician participation.

Membership in the underwritten programs increased by 106,457 (10.7%), bringing total enrollment to 1,097,045 at the end of the year. According to the latest figures available from the National Association of Blue Shield Plans (for the nine months ended September 30, 1968) the percentage of gain, well above the national average of 1.95%, was one of the highest in the country. The Maryland Plan is now the 16th largest among the 82 Plans in the United States, Puerto Rico, and Canada. At year's end our membership was 86.5% of that of our companion Blue Cross Plan, as compared with 82.5% a year ago.

The Plan intensified its efforts to convert as many subscribers as possible from the low fee schedule Plan A to either Plan B or the usual and customary fee program, Plan C. The success of the campaign is revealed by the year-end tabulation which shows that only 10.8% of total enrollment was in Plan A, as compared with the 17.6% of December 31, 1967.

Plan C enrollment increased substantially during the year. Including over 118,000 high-option Federal employees, effective January 1, 1969, total Plan C membership is well over 240,000, double the 120,000 of one year ago. Expressed in percentage of total enrollment, persons covered under usual and customary fee based contracts accounted for more than 22% of total membership.

Incurred claims during 1968 amounted to $20,553,000, an increase of about $2,354,000 over 1967. An average of 11,600 claims per week were processed during the year from our underwritten business, well above the 8,600 of a year ago. Medicare B claims payments amounted to $10,865,000, up by more than $1,898,000 from the previous year; the bill processing volume under this program was about 8,600 per week throughout the year. Another $677,528 was paid to Maryland physicians under CHAMPUS (Civilian Health and Medical Program of the Uniformed Services) last year.

The members of our Professional Relations Department made 3,686 visits to professional offices during 1968, helping materially to maintain the Plan's liaison with physicians and their office assistants. In addition, our representatives attended 18 meetings of county medical societies, specialty organizations, office assistants' associations, and medical secretarial student classes. At the end of the year 3,765 physicians were in participating status, representing 91% of those physicians currently submitting claims to the Plan.

Blue Shield also renegotiated its operating agreement with Blue Cross with the result that all personnel in those departments, engaged solely in Blue Shield work, were transferred to Blue Shield employee status on January 1, 1969.

Maryland Blue Shield lost two Trustees by death during the year—F. Ford Loker, MD, and C. Parke Scarborough, MD. Both gentlemen served Blue Shield well and faithfully; their passing is recorded with deepest regret.

The Board of Trustees joins me in expressing appreciation to the Plan's administrative staff for its many

contributions to the successful conduct of the Plan's business during the year.

Respectfully submitted,
J. Sheldon Eastland, MD

MEMBERSHIP COMMITTEE

Mr. President and Members of the House of Delegates:

There was no Membership Committee appointed and no meetings held this year.

Respectfully submitted,
William G. Helfrich, MD, *Chairman*

POLICY AND PLANNING COMMITTEE

Mr. President and Members of the House of Delegates:

An Ad Hoc Committee on Utilization Review in Nursing Homes and Extended Care Facilities was appointed by the Policy and Planning Committee. Invited guests and consultants attended a meeting of the committee.

The attention of the House of Delegates is called to the urgency of encouraging the formation of Utilization Review Programs throughout the state because of the wide variation in the quality of medical care in various nursing facilities. The experience of the Montgomery County Medical Society in coordinating utilization review of Extended Care Facilities in that county has proved the feasibility of such a program.

First, definitions of the three types of nursing homes must be clarified:

Nursing Home—Extended Care means any institution which renders skilled nursing care to persons suffering from disease or other disabilities. (Skilled nursing care includes care rendered by registered professional nurse or licensed practical nurse under the supervision of a registered nurse.)

Nursing Home—Long Term Care means rendering nursing care (by or under supervision of an RN or an LPN) to persons suffering from disease or other disabilities.

Personal Care Home means any institution which renders personal care (services which an individual would normally perform for himself but for which he is personally dependent on others because of advanced age, infirmity, physical or mental limitations).

After serious and searching discussion the following proposals are recommended for adoption as policy of the Medical and Chirurgical Faculty of the State of Maryland:

1. The function of utilization review in Extended Care Facilities should be administered on the local county or regional (group of adjacent counties) level. The Medical and Chirurgical Faculty's role should be one of information and guidance.
2. A committee of the Faculty (already existing or newly appointed if necessary) should be charged with gathering information concerning utilization review from all available sources and stimulating formation of local or regional review committees. This information, along with administrative suggestions should be available to any component society or group of societies requesting such.
3. It is recommended that the Medical and Chirurgical Faculty endorse, as Faculty policy, the principle of utilization review in all Nursing Home Facilities in addition to that required under State and Federal regulations as a means of assuring quality medical care for the patients in such nursing homes.

Arthur T. Keefe, MD, *Chairman*

MARYLAND MEDICAL POLITICAL ACTION COMMITTEE

Mr. President and Members of the House of Delegates:

Since Dr. Joe Hooper reported to you at this time last year on the Maryland Medical Political Action Committee, we have elected another congressman in Maryland. In last year's report, we stressed our determination to add a new face in congress. The contest was a close one but we won. As you know, this was Larry Hogan's victory in the Fifth Congressional District, which made our delegation in the House of Representatives four and four—a truly bipartisan representation in the State of Maryland. A total view of November '68 would show that we held our previous gains and added one to the score.

At the same time, for the first time, we got into a Senate race and found the experience very pleasing. Senator "Mac" Matthias was very cognizant of our help, and in him, we have a very sympathetic ear.

Now one of our best representatives has become chairman of his national party and, hence, our work next year will be vitally needed. We must find and elect his replacement; and so it becomes evident that our work seems never to be done. Finding new candidates and electing them while holding previous gains will go on year in and year out. Also, when we become active on the local scene as we would very much like to do, our work load will be increased considerably. The elections of 1968 are behind us and 1970 looms just around the corner.

You may be amazed to know that the American Medical Political Action Committee, which is our parent organization with headquarters in Chicago, ranks third in the nation's political action groups. We are just behind the national parties and COPE, which is labor's action arm. We would like to thank you for your political awareness in the past and ask you to sharpen it up as much as possible in the future. And I would like to close with a personal word. We have realized our goals in the past. We have set modest goals. These are to increase our membership to over 300 people and we are well over that now. We are here to stay. Secondly, we want and can now practice effective and coordinated candidate support. The candidates know who we are and want our support. And finally, we want to stimulate and educate ourselves and our members in politics and in this regard the newsletter, which last year was written by Mrs. Karl Mech, was a very great help indeed.

I would like, while still serving with this group, to see the leaders of state medicine, the members of the House of Delegates become members of this group. And I ask your support, and anyone who is interested in becoming active on the Board of Directors, we certainly

would like to hear from you because we need new faces and new help.

Respectfully submitted,
JOSEPH H. HOOPER, JR., MD, *Chairman*

COMMITTEE ON POSTGRADUATE EDUCATION, PREVENTIVE MEDICINE, AND PUBLIC HEALTH

Mr. President and Members of the House of Delegates:

This active Committee, through its many subcommittees, participated in numerous educational projects. During the 1968-69 year, eleven subcommittees and several ad hoc committees were appointed. To promote better liaison, representatives from the Regional Medical Program and from the Faculty's Emotional Health Committee were appointed to serve on this standing committee.

A new Subcommittee on Joint Anesthesia Study, which at this writing has not yet held any meetings, has been appointed upon Council recommendation. For many years there has been a Joint Anesthesia Study Committee of the Baltimore City Medical Society and the City Health Department, and now there is to be a similar committee on a State level, which will either encompass or will coordinate with the City committee. The City committee has acted as such a valuable teaching program that a state-wide study is certain to prove worthwhile.

William L. Stewart, MD, who was the Faculty's representative at the First National Conference on Continuing Medical Education sponsored by the AMA, gave a report at one of the committee meetings. This was obviously a most informative conference on the various areas of postgraduate education with many salient recommendations for state medical societies.

A symposium on "The 20th Century Adolescent" was held in November 1968 under the guidance of a special subcommittee, and arranged and supported financially by Geigy Pharmaceuticals. It is believed this was the most successful function of this type the Faculty has ever sponsored with an attendance at the afternoon session of over 1,300 and over 900 at the banquet. Many people were turned away because of the space limitations of the meeting facilities. In view of the outstanding success, Geigy Pharmaceuticals has made a tentative offer to sponsor another symposium in 1970.

Tentative plans are being considered for a symposium on infectious diseases to be held in the fall of 1969. This would be in conjunction with the National Communicable Disease Center.

It was agreed that whenever Council approval was desired in connection with a recommendation from a subcommittee, upon approval of this parent committee, the chairman of said subcommittee was to request permission to be present at the Council (or Executive Committee) meeting to discuss the matter involved and answer questions.

Subcommittee on Airport Medicine:

The chairman of this subcommittee personally conducted an investigation regarding the medical facilities at Friendship Airport. The managers of the four largest airlines, who he contacted, all agreed that the lack of physicians in the airport is of concern to them in terms of incoming passengers and accidents to their own employees. Various means of handling the situation were discussed, but nothing can be considered until the new State Airport Authority has been established. A resolution, which was passed by this committee regarding adequate medical coverage at Friendship Airport, received Council approval, and the chairman of the State Airport Authority was notified. The subcommittee is continuing to direct its efforts toward this problem as well as to consider what can be done about medical coverage for the many small airports throughout the State.

Subcommittee on Alcoholism:

This subcommittee was instrumental in having the Alcoholism Control Bill passed at the 1968 session of the State Legislature. However, the companion bill, which would have provided funds for implementing the bill was not passed. This incongruous action refuted the usefulness of the bill passed, but efforts are currently being made to correct this.

The subcommittee obtained Faculty approval for sponsorship of a seminar on "The Physiological Aspects of Alcoholism." This was held at the Belvedere Hotel in May and, while the attendance was considerably less than anticipated, it was most enthusiastically received by those who were present. Four hundred copies of the Manual on Alcoholism were distributed to Faculty members at the 1968 Annual Meeting. A local judge, who is concerned about the problem of alcoholism, has been invited to join the subcommittee as a consultant.

Members of the subcommittee participated in a seminar held at College Park to train personnel to work with alcoholics. They also participated in a conference, cosponsored by the Faculty, to discuss implications for general hospitals of the "Comprehensive Intoxification and Alcoholism Act." Another conference which this subcommittee sponsored was on the "Treatment of Acute Phases of Alcoholism Including Delirium Tremens."

Two motions have been passed and submitted for Executive Committee approval to the effect that the Faculty endorse the 1970 fiscal year budget of the Department of Mental Hygiene to support the alcoholism program through the Community Mental Health Program; and that the Faculty support legislation providing for State financing of Community Health Programs, including alcoholism.

Subcommittee on Cancer:

The Faculty Council adopted the recommendation of this subcommittee that a study be made regarding a central cancer registry provided it were on a voluntary basis. The Subcommittee felt that a registry on a voluntary basis would not be workable. The Council disapproved the recommendation, because of lack of information, that the Faculty sponsor cancer detection workshops.

Child Welfare Subcommittee:

A school examination form which originated within this subcommittee and the State Mental Health Department, after careful study and minor revisions, received Council approval. It has now been approved by the State Board of Education and will be put into use at the school term beginning in the fall of 1969.

The recommendations of an Ad Hoc Committee on PKU Legislation was adopted by the Council. The statement regarding the distribution of mumps virus vaccine, as recommended by the American Academy of Pediatrics, was endorsed by the Faculty. The subcommittee is in accord with a bill that has been introduced in the State Legislature regarding required immunizations before admission to school, but does not feel that specific immunizations should be spelled out in a law.

Council approval was received for evaluation to be made of a hearing and vision screening program for three- to five-year-old children in Maryland. An Ad Hoc Committee has been appointed for this purpose.

Ad Hoc Committee on Hearing and Vision Screening:

Serving on this committee, in addition to pediatricians and an otolaryngologist, are several audiologists, and the Executive Director of the Maryland Society for the Prevention of Blindness. This study is being made, upon Council recommendation, following the publicity received about a program in Minnesota, as many requests for information about such a program have been received in the Faculty office. There is no problem involved with the vision screening as this can be carried out by the Maryland Society for the Prevention of Blindness. However, there are many factors to be evaluated in connection with the hearing screening. The program would involve well-trained volunteers. A detailed, thorough study is in progress at present, and it is hoped by September 1969, specific recommendations can be made. It is definitely felt that this will be a most worthy project and an extremely good public relations activity for the medical profession.

Subcommittee on Chronic Respiratory Diseases:

Of prime consideration to this subcommittee has been the situation regarding beds for tuberculosis patients in Maryland. It is a recognized fact that, while the number of tuberculosis patients is on the decrease, Baltimore has one of the highest rates in the country. The current problem has arisen out of the reduction of the number of beds at the Baltimore City Hospitals from 150 to 90, and more patients being referred to Mt. Wilson, which is solely a TB hospital. The latter is a State-supported hospital while the former receives reimbursement in the same amount as the cost for patients at Mt. Wilson. However, the cost of maintaining a patient in the City Hospitals is higher and the difference must come from City funds, which are being curtailed. Patients at Mt. Wilson, who have medical and/or surgical conditions in addition to TB, must be treated at another facility, which is not the case at City Hospitals. Decision is pending as to whether TB patients are to be handled at only one hospital and, if so, which of the two aforementioned will be selected. The State has requested budget funds to establish TB units in certain general hosptials since eventually there may not be sufficient patients to warrant special hospitals.

A motion was referred to Council to the effect that this is a problem of concern to the Medical and Chirurgical Faculty, and that the Faculty go on record as approving the continuation of the care of TB patients at Baltimore City Hospitals. Council, after careful consideration, adopted a motion that the President of the Faculty appoint an ad hoc committee to consider this matter. At this writing no further report has been made available.

A seminar is being planned on respiratory diseases, of which the Faculty is to be one of the co-sponsors with the USPHS supporting it financially. The Chairman of this subcommittee is chairman of the planning committee for the seminar.

Subcommittee on Diabetes:

Council approval was received on a motion that the Faculty endorse the principle of an annual Diabetes Detection Drive, with the understanding that local component societies be free to implement this at their pleasure. A letter was sent to each component society asking it to organize a Drive on a local basis. The Drive in November 1968 was most successful in Baltimore city, but no record is available as to how much was done in each county.

The chairman has requested each component society to appoint someone to serve on this subcommittee to work with health department officers in arranging future Diabetes Detection Drives. The Chairman also recommended that each year the President of the Maryland Diabetes Association also be chairman of the Faculty's subcommittee. No action has been taken on this.

Subcommittee on Maternal Welfare:

The Council adopted the Guidelines for Hospital Medical Staffs for the Performance of Therapeutic Abortion, which were set up by an ad hoc committee after the Law was passed at the 1968 session of the State Legislature. The Law went into effect in July 1968 and a copy of the Guidelines was sent to every member of the Faculty and to every hospital in the State. The State Board of Health and Mental Hygiene, upon the recommendation of the Faculty, appointed this subcommittee as an advisory committee on this subject to the Board. In view of this, a psychiatrist was appointed to serve on the subcommittee. A request was also forwarded to the State Board, and approved, that it work with the Faculty on the development of a reporting form for all therapeutic abortions. This form was prepared and distributed to all hospitals in the State.

A motion was submitted by this subcommittee to the parent committee that "Continuation of a pregnancy in a 15-year-old or under may represent a grave impairment to the mental health of the mother and, therefore, warrants a psychiatric evaluation." This evolved from the concern of the Baltimore City Health Department about pregnancies in the younger teen-agers who might require a therapeutic abortion. The motion was referred to the Faculty's Emotional Health Committee for an opinion. That committee submitted an amended version of the motion and this has now been sent to the Council of the Faculty for approval. The amendment was in the last part of the motion, which now reads ". . . warrants an evaluation for the possibility of a therapeutic abortion."

An Ad Hoc Committee on Perinatal Mortality has been appointed and is most active. It is composed of members of this subcommittee and members of the Subcommittee on Child Welfare. A questionnaire of vital statistics on perinatal deaths is now in the process of being prepared. A scientific exhibit will be displayed by this Ad Hoc Committee at the Annual Meeting of the Faculty in April. This exhibit will contain the minimum resuscitation equipment necessary in a delivery room, information on the Apgar procedure, etc., and is being supported by funds from outside sources.

This subcommittee continues to review all maternal deaths in the State. The causes of death, by diagnosis, in these obstetric patients are reported. The 1967 report was completed too late for inclusion in the 1968 annual report and is as follows:

Table 1

CAUSES OF MATERNAL MORTALITY

	White	Nonwhite	Total
Infection			4
Postabortal		3	
Puerperal			
Peritonitis	1		
Other			5
Cerebral Hemorrhage	2	2	
Unknown	1		
Hemorrhage			3
Ruptured Ectopic		2	
Post Partum			
Ruptured Uterus		1	
Embolism			2
Pulmonary	2		
Amniotic Fluid			
Toxemia			0
Eclampsia			
Unclassified			
Total			14

Table two shows the maternal deaths occurring in Baltimore and the counties:

Table 2

MATERNAL DEATHS ACCORDING TO RACE & SUBDIVISION

	Baltimore	Counties	Total
White	1	4	5
Nonwhite	7	2	9
Total	8	6	14

It is interesting to note that in Baltimore five of the deaths occurred in nonviable pregnancies. Three were infected abortions and two were ruptured ectopic pregnancies. In the counties, all maternal deaths occurred in viable pregnancies. Out of the six deaths in the counties three were voted preventable and no determination could be made regarding a fourth since the patient died unattended and no autopsy was obtained.

Of the city deaths, three were due to infected criminal abortions and obviously preventable. In all, six of the fourteen deaths were voted preventable, and of these, in all but one case, the preventability was believed the responsibility of the patient. It would therefore appear that through health information and education we might possibly reduce this maternal mortality by nearly 50%.

It is of further interest to note that there were no maternal deaths from toxemias, usually one of the three leading causes.

Subcommittee on Continuing Medical Education (MEDIC):

The MEDIC network continues in operation with a complement of thirty-eight community hospitals, plus outlets at the Hospital Council of Maryland, State Department of Health, the Medical and Chirurgical Faculty and the Baltimore County Health Department. In addition, equipment has been installed at the Headquarters for Civil Defense in the State of Maryland. The purpose is to allow the network to be used for interhospital communication in the event of a civil emergency. The network was put to such a use during the riots of Baltimore city, April 1968.

The expenses for the MEDIC network have remained constant but the cost to the Medical and Chirurgical Faculty has been reduced by 50% due to a grant supplied by the Merck, Sharp and Dohme Pharmaceutical Company. A similar grant has been promised for the coming year.

Approval by the House of Delegates is requested on the following recommendation:

> **That the MEDIC Network be continued and that sufficient funds be appropriated to the extent needed to finance the operations for the coming MEDIC year.**

Programs offered over the MEDIC network have included a weekly medical lecture which is rebroadcast on three separate occasions during the following week, medical rounds presented weekly from the University of Maryland Hospital, and both medical and pediatric rounds presented weekly from The Johns Hopkins Hospital. A program of CPC's is offered on a weekly basis originating from The Johns Hopkins Hospital. Use has been made of the MEDIC network for program presentation by the School Health Committee of the Maryland Chapter of the American Academy of Pediatrics, the Committee of Joint Anesthesia Study of the Baltimore City Medical Society and City Health Department, the Baltimore City Medical Society, and the State Health Department. Committees of the Faculty have also used this facility for meetings and announcements.

For the next year modifications in program planning will be made based on the experience of the past and projected needs for the future.

Subcommittee on the Medical Aspects of Sports:

Approval of Council was received for a physical examination form and guidelines for medical evaluation of candidates for school sports activities. At present, these forms are in the hands of the Board of Education awaiting approval and implementation. A reporting form for sports injuries is also being considered within the subcommittee. This will make possible a study of the epidemiology of sports as to what injuries occur in connection with specific sports and in what schools they occur most frequently.

The second annual seminar on the Medical Aspects of

Sports was held at the Catonsville Community College in August 1968. There were 189 in attendance and only $68.28 of the $200 allotted by the Faculty was spent. The third annual seminar is scheduled for December 1969 for which the Faculty has agreed to allot up to $300, contingent on the subcommittee giving consideration to the sale of exhibit space—the income from which would help underwrite the cost of the program. It is planned to sell exhibit space, as there were many interested companies in 1968.

Speakers' Bureau Subcommittee:

This subcommittee, which will provide speakers for medical and paramedical groups, has not received any requests this year, even though the availability of speakers has been publicized within the Society.

Subcommittee on Traffic Safety:

A most successful seminar was held in May 1968 with leaders of various professional and lay organizations. As a result of this seminar, an organization has been formed which is known as the United Organization for Traffic Safety. This is to be a continuing organization that each year will concentrate on one or two traffic safety bills. One of the bills on which effort is being focused at the 1969 session of the State Legislature is "Implied Consent." Maryland is apparently behind other states as far as this law is concerned—17 states already have such a law in effect. The only other area in which Maryland is behind is in a reportable disease law, but the Department of Motor Vehicles is planning to include on the driver's license renewal application that the driver is responsible for reporting any diseases or physical disabilities he may have. In other areas of traffic safety legislation Maryland is ahead of most states.

The Visual Acuity Bill, which the Faculty supported in 1968, was passed by the State Legislature at that time.

This subcommittee now has a monthly page in the Maryland State Medical Journal devoted to various aspects of traffic safety. One issue of the Journal has had a traffic safety related cover, which was submitted by this subcommittee. The October 1969 issue will be dedicated to the medical aspects of traffic safety.

From this report it is obvious that the committee and its many subcommittees have been engaged in numerous worthwhile projects valuable to both the profession and the public.

I am most happy and appreciative of the privilege of having served as chairman for the past two years. My sincere thanks go to each member of the committee and each subcommittee member for the time and effort expended in the interest of postgraduate education, preventive medicine, and public health.

Respectfully submitted,

John Whitridge, Jr., MD, *Chairman*
Ruth W. Baldwin, MD
Robert G. Chambers, MD
H. Garland Chissell, MD
Irvin H. Cohen, MD
John B. De Hoff, MD
